Melting icebergs

More and more people are finding JEOL gives them maximum capability -

...shouldn't you take a close look at what JEOL can offer

Top left: TEMSCAN. Total analytical capability in electron optics, including TEM, STEM, SEM, NDS and ELA.

Top right: JEM-100S. Cost-effective routine TEM with high performance, yet simple to operate.

Centre left: JSM-T20. The best routine, low-cost SEM available, with built-in micron marker and function checker.

Centre: JSM-35. Multi-purpose, high resolution SEM with total X-ray analysis capability.

Centre right: JSM-25. Routine, versatile high performance SEM with unique easy operation features.

Right: FX Series. High performance and versatility for FT-NMR.

RP397

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

At the beginning of 1978 a new copyright law comes into effect in the United States. Single copying of *Nature* articles and letters for personal purposes is allowed under the legislation, as, under certain circumstances, is multiple copying for class-room use. On the other hand, all other copying in the U.S. is subject to restrictions. If copies are to be made for resale in any way, a written request must be made to us; if the copying is for any other purpose, consent is granted if the copier pays the appropriate fee to the Copyright Clearance Center, Inc., c/o AAP, One Park Avenue, New York, NY 10016 for articles and letters bearing a code number at the foot of their first page. The fee for each copy of an article or letter reproduced is US\$1.00. In all other countries, single copying for personal purposes and multiple copying for non-commercial class-room use is permitted but other copying requires written permission from us.

UNCSTD—not just for bureaucrats

IN mid-1979 the United Nations will be convening a conference on science and technology for development (UNCSTD), probably in Vienna. It will be a large affair and can be seen as a successor to, and in some ways a consolidation of the earlier conferences on environment, population, food, women, habitat, water and deserts. Indeed those with long memories may recall that in 1963 the United Nations convened a similar large assembly in Geneva on 'the application of science and technology for the benefit of the less-developed areas'—a conference which left a very modest heritage. Many are wondering whether the 1979 conference will be any better than yet another forum for high-flown sentiments, thinly veiled abuse and meaningless resolutions. What happens in 1978, and particularly what scientists do for themselves will help to decide whether the meeting rises above the level of a circus.

UNCSTD is not about science and technology *per se*, it is about national and international policy on these matters. There are four expressed main objectives:

- to decide on ways and means to apply science and technology in establishing a new international economic order,
- to strengthen the technological capacity of developing countries to enable them to apply science and technology to their own development,
- to realise scientific and technological potential in solving development problems of national, regional and global significance, especially for the benefit of developing countries, and
- to provide instruments of cooperation to developing countries in the use of science and technology for solving socio-economic problems that cannot be solved by individual action.

Talk of a 'new international economic order' does not, of course, exactly commend the conference to those developed nations which are suspicious of this concept;

even so, they, along with developing nations, have received a detailed request for the submission of national papers relevant to the conference and it is from these papers, together with the proceedings of regional conferences now being held, that the detailed agenda for UNCSTD will be forged.

The value of such a conference is undoubtedly that it causes some important people in government to have to stop and think about policy or lack of it. In this way the application of science and technology for development might no longer be regarded as a bit of an insignificant backwater in the developed world or as something which has to undergo violent changes in its level of support in the developing world.

The weakness of UNCSTD, however—or at least its potential weakness—is that scientists and technologists may not get a look in; the conference could be entirely bureaucrats talking to bureaucrats. It is possible for this to happen; the conference's secretary-general, Joao da Costa, a Brazilian scientific diplomat, fully admits in a recent issue of *Development Forum* that the secretariat has no authority to bypass governments and go directly to the masses—all it can do is encourage governments to hold discussions with scientists, trade unions, professional organisations and so on. Thus the voice of the practitioner need only be heard if the government chooses to ask for it.

There is, therefore, a need this coming year for scientists and technologists to speak up and use every channel that is open to them to tell their colleagues, in their own countries and around the world, how science and technology is being used and how they think it should be used for development. This was an appeal made very clearly and eloquently in *Nature's* columns recently by Michael Moravcsik of the University of Oregon (24 November, page 228) and we hope that his message will encourage more people to toss their ideas into the arena. Certainly *Nature* will try to be receptive over this coming year to those in the developing world who wish to speak to a large audience. □

Out of the frying-pan into the PWR

Amory B. Lovins, a consultant physicist, and British Representative of Friends of the Earth Inc., the US sister-group of the independent UK group FOE Ltd., argues that US pressurised water reactors are an economic disaster

THE juggernaut advance of light-water reactors (LWRs), and especially pressurised-water reactors (PWRs), through world nuclear markets has seemed to their promoters a sort of manifest destiny. When Britain rejected PWRs for the second time, in 1974, the president of Westinghouse, which first developed them, replied magisterially that this was only "an interim solution, as we are not convinced that it addresses Britain's long-range energy needs." Since then, British electricity use has risen by less than 2%, while excess output capacity above a reasonable 20% reserve margin has risen to 20% of peak output and may soon be 30 to 45%. Closer analysis of energy use has also revealed not only that far more efficient use and even proven renewable sources are practicable and advantageous, but also that Britain already has twice as much electricity as is needed for the premium uses that can give value for money from this very costly, high-quality form of energy. Yet Westinghouse and its allies—including European vendors, the National Nuclear Corporation (NNC), and the Central Electricity Generating Board (CEGB)—are now back again. They argue that the British preference for advanced gas-cooled reactors—the last major indigenous programme of thermal reactors outside Canada—is a sentimental anomaly that now, bereft of further excuses, must give way to technical and economic rationality.

In an open letter to the Prime Minister of the United Kingdom, James Callaghan, on 21 December, Friends of the Earth document a counter-argument. They suggest that the worldwide dominance of PWRs has arisen not from merit but from aggressive salesmanship and "a process of 'mutual intoxication' whereby US promotional institutions persuaded each other, then their counterparts abroad, that LWRs' supposed merits were real and had been demonstrated when in fact they had not and still have not been realised: the distinction between promotional prospectus and critical evaluation was completely obscured". Thus, according to a forthcoming study*, the gas-graphite system displaced in France by PWRs was in retrospect superior, but policy-makers were caught up in a skilfully propagated and wholly unfounded PWR euphoria. Systematically mistaking hope for fact, they thought they *knew* how much PWRs would cost to build and to run, how reliable they would be, and what fuel burnup they would attain. US experience has fallen far short of these expectations. Real capital costs have averaged more than twice as high as promised; real fuel-cycle costs will be about six times as high. Capacity factor has averaged 20 to 30% lower and burnup 20 to 40% lower than forecast. The picture is not getting brighter. Two recent studies, for example, show PWR capital costs rising by 20% y^{-1} or \$188 $kW(e)^{-1} y^{-1}$ in constant 1976 dollars—about three times as fast as coal-fired stations. Much European and Japanese experience is similarly disappointing. Yet NNC's latest report on reactor choice is not an analysis of independently established facts so much as a seller's advertisement of alleged virtues. It is remarkably like the promotional paper that USAEC staffers drafted for the European Community's "Three Wise Men" when they recommended twenty years ago that Europe switch to LWRs.

*Light Water: How the Nuclear Dream Dissolved (New York: Basic Books, March 1978), by Professor I. C. Bupp (Harvard Business School) and Dr J.-C. Derian (an official of the French regional development ministry DATAR).

In the US, the euphoria has worn off abruptly. The doubtful economics of real (as opposed to paper) PWRs, uncertainties about demand, reliability, and safety, and the macroeconomic problems of a capital intensity 10 to 30 times that of new North Sea oil capacity have together led to what FOE call "the most dramatic collapse of a major industrial enterprise in history". US yearly domestic orders in 1972–6 (net of cancellations ascribed to the year of original ordering) were respectively 28, 38, 17, 5, and 3 reactors. In 1975–6, seven reactors were ordered, eight cancelled, and 13 deferred (six indefinitely). In 1977, two were ordered, four cancelled, and 26 deferred. This quickening disintegration has led Dr Schlesinger's deputy to state that "the nuclear option has essentially disappeared" in the US.

Official forecasts of US nuclear capacity in the year 2000 have been falling so quickly that, extrapolating linearly, the 1978 forecast for 2000 should be zero (in fact the asymptote might be as high as 24% of present US delivered energy use, or about the level of firewood). Nuclear expectations are likewise plunging in France, Germany, the UK, Japan, and elsewhere at such a rate that the 1979 forecast of 1985 OECD nuclear capacity should be zero. In Canada, which has had none of the US regulatory problems, forecasts have dived just as steeply as in the US, suggesting that the cause is not some political artifact but fundamental market forces—which President Carter's energy policy does nothing to discourage and much to reinforce. In short, PWRs are proving all but unsaleable throughout the industrial world. Staunching the rapid haemorrhage of money and staff from reactor vendors is requiring proliferative exports to developing countries, lavishly subsidised by exporting governments. This is not much of a vote of confidence in PWRs or in Britain prospects for profitably exporting them. Indeed, reports in the financial press suggest that no LWR vendor has sold reactors at a profit: vendors' cumulative losses are said to exceed £1 000 million in the US (over half of it for Westinghouse alone), £250 million in Japan, over £200 million in West Germany, and large but undisclosed sums in France and elsewhere. This hardly seems a promising line for Britain to follow—salvaging and refloating other countries' lame ducks.

Further, while PWR advocates consider the vexed question of pressure-vessel rupture adequately resolved, FOE (like most US observers) have long put this issue rather far down a very long list of serious safety problems. Their letter documents ten compendia showing over 200 unresolved major safety problems of PWRs, most of them officially acknowledged. British advocates' optimism about PWR safety may rest not on the detailed knowledge which they claim, but on the lack of it which they have in the past displayed (notably in the 1973–4 controversy) and which the uncharitable can infer from the 1977 NNC report. It is possible that the NNC, CEGB, DOE, and Nuclear Inspectorate staff have in fact all done their home work. There is, however, no published reason to believe this is the case. They may still not have consulted the main original sources, preferring to rely, as in 1973–4, on summaries prepared by US parties that could hardly be considered disinterested. FOE have therefore proposed that specified papers well known in the US debate be the subject of public colloquy in Britain between highly qualified US critics and their British adversaries.

Only four years ago, the NNC and CEGB were pressing for an urgent programme of 32 PWRs—which, if adopted, might well by now have pushed the British nuclear industry over the brink of ruin. The advocates of haste that time were wrong; the advocates of caution were right. So it may be again.

German leader for JET project

Dr Hans-Otto Wüster, a West German accelerator physicist presently on the directorate of CERN, was named on 20 December as project leader for the building of JET, Europe's planned giant torus for extending fusion energy research. Dr Paul Rebut, the French physicist who has led the design team for JET, has been named deputy, and Dr Romano Toschi (currently head of the Italian fusion effort based at Frascati) will be Chairman of the Management Committee. All three appointments are provisional, but are expected to be adopted formally by the Council of Ministers early in 1978.

Dr Wüster's appointment is bound to be felt as somewhat of a rebuff to Rebut: but it was not unexpected. This is not because of any failing in Rebut, but because of the vexed European politics that have dogged JET from its inception. When the decision was made last year that JET should come to the Culham fusion laboratory in the UK (where Rebut's design team had been based) rather than to Garching in West Germany, it was felt that some kind of recompense should be paid to Germany. The appointment of Wüster to the top job achieves this—if to the chagrin of France.

Wüster is not well known at Culham—his field has been high energy physics, not fusion—and he

may find his initial reception cool. But he has time yet to work out his relationship with Rebut and Toschi and those of the design team still left at Culham. The Interim JET Council that appointed him, composed of representatives of all the nations contributing to JET, is suffering from the usual problems of large international committees and is not making its decisions particularly rapidly. It seems unlikely that the team will be completed before July, and meanwhile the main competitor—The Princeton Tokamak—has a chance to forge ahead. After all the earlier delays in the JET project Culham staff look on this further constraint somewhat resignedly.

Wüster himself is no stranger to large international scientific projects. He was deputy to John Adams during the building of the 400 GeV SPS accelerator. Once it was agreed to build it, the SPS became a great European success—built under budget, ahead of schedule, and beyond specifications. Wüster managed the budget of the SPS, and no doubt his success there influenced the JET Council. It will be interesting to see if he can be successful with the budget and management of JET, in a technology he knows less well.

Staff at CERN respect Wüster as a man with great administrative ability, a man who has his goals very clearly

Hans-Otto Wüster: goals clearly in mind

in mind, a blustering, jovial man "who will pile in rapidly" and take to his job with enthusiasm.

Another undoubted asset Wüster will bring to JET is his long-standing friendship with his opposite number at Princeton: Dr Paul Reardon who heads the Princeton Tokamak team. Reardon was also a high energy physicist; and he played a similar role to Wüster's in the building of the Fermilab National Accelerator, the 400 GeV US competitor to Europe's SPS. Fermilab was built first, and skimmed the cream, because of the delays that hit CERN in finding a site and funding in Europe. Wüster will no doubt go all out to prove that Europe can, sometimes, be first.

Robert Walgate

Construction shares

ONE of the most pressing tasks the UK research councils will have to tackle early in the new year will be to decide how to spend their individual allocations of the money promised them late last November and early December for construction and energy conservation. Firm decisions must be made very soon because the money has to be spent in 1978-79.

The Advisory Board for the Research Councils (ABRC) announced its decision on how to divide the total sum between the individual research councils just before Christmas: a total of £4.5 million had to be shared between four research councils (the Social Science Research Council did not put in a bid) and the British Museum (Natural History). Initially, £4 million had been set aside for the recipient bodies of the science budget to spend on construction during 1978-79; but in December, when the Secretary of State for Energy announced the UK's £320 million energy conservation programme, the sum was increased to £4.5 million. £1.1 million of it is to

be spent on energy conservation.

The £4.5 million has been divided as follows: the Agricultural Research Council is to receive £1.07 million, of which £0.27 million is for energy conservation; the Medical Research Council, £0.73 million, of which £0.13 million is for energy conservation; the Natural Environment Research Council, £0.65 million, of which £0.15 million is for energy conservation; the Science Research Council £1.75 million; and the British Museum (Natural History) £0.3 million.

The Natural History Museum probably has the firmest plans of what to do with its share. Most of it will be used to provide accommodation for fossil collections and staff at the museum's station at South Ruislip whilst preparations for a new exhibition hall in part of the main building get underway.

As yet, however, the research councils claim to have few firm plans for spending their shares, even though they must each have put forward definite proposals to the ABRC. But they do agree that major new capital projects are out of the question:

the fund is too small and the time available too short. Most of the money will be spent on extending or improving existing buildings or speeding up construction work already started. For example, the SRC will use some of its share to speed up work on the nuclear structure facility at the Daresbury Laboratory and to extend some of its central user facilities. The NERC may use some of its share to put into operation existing plans to extend facilities at the Institute of Hydrology.

Judy Redfearn

BBC commemorates Bronowski

GEORGE Steiner, a controversial man of letters and champion of science, who learned physics from Enrico Fermi and chemistry from Harold Urey, will broadcast live in the UK on BBC2 television next Tuesday at 8.10 pm in the first Jacob Bronowski memorial lecture. Bronowski, devoted to what he called 'the democracy of the intellect', literally gave himself to an epic tele-

vision series—"The Ascent of Man"—which presented his personal and heroic view of science as the saviour of mankind. Bronowski died shortly after completing the programme; these lectures are the BBC's tribute to him.

Steiner is an interesting choice to lead off the memorial lectures. He has many points of contact with Bronowski; and as many differences. Both were Jewish exiles from Europe: the Nazi holocaust is writ large in both their lives, and both have shown themselves aching to find escape from it. The ultimate intellectual sanctity of science, with its references to verifiable fact, particularly in the physical sciences and mathematics, appealed deeply to both men as the antithesis of dogmatism. But whereas Bronowski searched for a release, in the fashion of The Enlightenment, for all of mankind, Steiner appears to look only towards an elite, a bright spark in the

darkening eclipse of humanity.

Steiner will argue in his lecture that it is pointless to look for controls on the pursuit of science; for knowledge will out, somewhere, sometime. One day scientists will make their test-tube babies. One day there will be genetic engineering of human beings. We are powerless against the march of truth. Steiner will prove himself the hawk of science, where Bronowski was the dove. In the process he may do science a disservice. He is a great acquirer of knowledge: "What else is there?" he asks. Bronowski also asked for compassion, an emotion that Steiner might be suspected of dismissing as romantic.

In the 'Ascent of Man' Bronowski drew attention to a man who he said was the most intelligent he'd known: Johnny von Neumann, the originator of games theory. Von Neumann failed mankind, said Bronowski, as an intellectual elitist who believed

not in the democracy but the aristocracy of the intellect. Steiner appears to fall into the same mould as von Neumann.

Steiner learned science at the University of Chicago in the late 1940s. He "scraped" a first and to his lasting regret was turned away from science by his careers advisor who said he could not cope with physics (but that was Chicago in the days of Fermi; Lee and Yang were students) and that the rest of science was "bottle-washing". Steiner, fluent in four languages, turned to journalism and ultimately to the study of language.

He would have liked to have been a biologist. His passion is mathematics and his heroes are mathematicians. The creation of melody, and of proofs (in mathematics) that the truth of a certain proposition is undecidable, are, he believes, the greatest mysteries.

Robert Walgate

ESA names European candidates for first Spacelab mission

THE European Space Agency (ESA) has named the four candidates from whom one will be selected to serve, along with one American scientist, as a "payload specialist" on the joint US-European Spacelab mission scheduled for the second half of 1980. The candidates were presented at a press conference on 22 December at ESA's headquarters in Paris. They are Franco Malerba, 31, an Italian electronics engineer and physicist; Ulf Merbold, 36, a West German physicist and staff member of the Max Planck Institut für Metallforschung in Stuttgart, where he has been researching crystal lattice defects; Claude Nicollier, 33, a Swiss astronomer; and Wubbo Ockels, 31, a Dutch physicist who is doing research at the Nuclear Physics Accelerator Institute in Groningen.

With the exception of Malerba, all are married with one child. Ockels is the only non-flier in the group. Merbold is a glider pilot, Malerba holds a private pilot licence and Nicollier, after working as a professional pilot for Swiss Air, is still in the Swiss Air Force.

After three months of Spacelab familiarisation at European facilities and further evaluation in Houston, one of the four candidates will be eliminated. After next May the other three will continue training until a few months before the flight when one of them will be chosen to be the first European to travel and work in earth orbit. The other two will act as back-up specialists on the ground. On the first ESA/NASA mission lasting one week, the two scientists will be responsible for a payload of 76 experiments in the fields of materials science, atmospheric physics, life sciences, solar physics,

astronomy, earth observation and space technology.

"We were not looking for a superman or superwoman," said Michel Bignier, Director of the Spacelab programme. He explained that the scientists would be working in a pressurised "shirt-sleeve" atmosphere. Nonetheless, the evaluation criteria had been particularly severe—equivalent to level II criteria used by NASA to select permanent mission specialists. "Nobody wanted to run the risk of a rejection by NASA," added Mr Bignier.

By last September, 53 candidates had been preselected from 2,000, including 35 women, who had responded to ESA's announcement of opportunity issued in April. One woman, Anny-Chantal Levasseur—regourd of France, was among 12 finalists but failed on the last medical test.

Candidates were screened by four panels of experts covering general

assessment and system engineering, scientific, psychological, and medical tests. All the candidates agreed that the psychological testing, carried out at the DFVLR Institute for Flight Medicine in Hamburg, was particularly arduous. Klaus-Martin Goeters, a member of the institute and head of the psychological panel said that tests were aimed at ensuring that those selected could cope with the stress created by the heavy Spacelab workload and the unusual environment. Drawing a typical personality profile, Dr Goeters described the successful candidate as "someone who is highly motivated, with a tendency to be an introvert, preferring small groups to a larger social context, who is unpretentious in habits and life style, thus capable of envisaging certain privations, and is highly mobile: that is a person interested in and looking for new things—with, you might even say, a taste for adventure".

Claude Nicollier, Ulf Merbold, Wubbo Ockels, Franco Malerba: Europe's spaceman scientists

GMAG: Stormy weather ahead?

1978 may prove to be a difficult year for Britain's Genetic Manipulation Advisory Group. David Dickson reports

GMAG, which was set up by the UK Government following concern at the implications of research into the genetic manipulation of micro-organisms, celebrated its first birthday last month, thereby reaching the half-way stage of its first term of office. So far both scientists and trade unionists have given it, in general, a clean bill of health; comments on its performance range from "as good as could be expected" through "better than anticipated" to "a highly successful experiment".

Applications for more than 80 experiments, from about 25 different institutions, have been received, and all have been approved. According to Sir Gordon Wolstenholme, director of the CIBA Foundation and chairman of GMAG, the first year has been "surprisingly profitable and useful".

Yet if the first year has been relatively calm, there are storm clouds on the horizon. Two factors in particular are likely to put pressure on GMAG's activities in the near future, and to test its skill in treading a delicate path between different—and sometimes opposing—interest groups.

The first of these factors is industry's rapidly growing awareness of the financial rewards offered by genetic engineering techniques, from the production of artificial hormones to, possibly, new plant crops. Already seven major US companies have established recombinant DNA research laboratories, and several British companies, after a relatively slow start, are jumping on the band-wagon.

The second factor is the additional knowledge, both about genetic structures and the potential hazards of their manipulation, that has emerged in the four years since a temporary moratorium was first suggested by US scientists. This knowledge suggests that some of the initial reaction was over-cautious, and that current guidelines might be "safely" relaxed.

Of these two, it is the industrial applications that have so far impinged most directly on GMAG's activities, primarily through the issues of confidentiality. For genetic engineering is rapidly becoming a field in which the dividing line between science and commerce is frequently indistinguishable.

In the US, for example, shortly after a team of San Francisco scientists headed by Dr Herbert Boyer confirmed that it had successfully inserted into bacteria a gene capable of producing the hormone somatostatin, a small Californian company Genentech an-

nounced that it would be using the technique to produce somatostatin for sale to research organisations and pharmaceutical companies by mid-summer 1978, at a cost considerably below the current market price.

In Britain, the National Research and Development Corporation—the body responsible for patenting and exploiting the results of government-sponsored research—recently held a lively and well-attended meeting for university scientists on the potential applications of genetic engineering. NRDC has already awarded a research contract to the John Innes Institute near Norwich for the study of improvements in the production of the antibiotic streptomycin, and other projects are in the pipeline.

Although some companies, such as ICI, have been studying the applications of genetic engineering techniques for a number of years, little is publicly known about how far such work has progressed. For with the potential rewards so enormous, not only commercial companies, but all those with potentially-patentable techniques, are keen to play their cards as close as possible.

There is therefore an inevitable reluctance to reveal even in outline details of future research programmes to a group such as GMAG over whose use of the information—notwithstanding the Official Secrets Act—an individual company can exercise no direct sanction.

The confidentiality issue is one which the difficulty of reconciling "health and safety" factors against "national interest" has provided GMAG with some uncomfortable moments. In particular, the four trade union representatives—two from the Association of Scientific, Technical and Managerial Staffs (ASTMS), one from the Institute of

Professional Civil Servants, and the medical officer of the Trade Union Congress—while respecting the need to maintain confidentiality for commercial reasons, have refused to be bound by any secrecy agreement which might prevent them from serving the interests of their members.

Many hours of discussion have been spent trying to devise a formula by which secrecy can be guaranteed for research programmes which must soon, under new health and safety legislation, be reported to the Health and Safety Commission. Eventually a compromise formula has been agreed under which, for a trial period of six months, members of GMAG will agree to a simple secrecy pledge, and applications for commercially-sensitive experiments will be seen by all except those considered to have some direct interest.

But for most scientists, the confidentiality issue, apart from interfering with claims for scientific precedence, remains largely peripheral. Of far greater concern is the type of pressure that may be put on those responsible for maintaining safety guidelines as a result of industry's interest.

In particular, many fear that industry's desire to pursue and exploit the applications of such research as quickly as possible may result either in pressure on governments to reduce containment requirements too far, or to remove them altogether, leaving the management of risk to the vagaries of the market place (and the accountancy skills of insurance companies).

There are already pressures from scientists themselves to rationalise present containment levels, bringing them more in line with procedures adopted for other types of experiment using known pathogens, and taking into account both the development of new genetic engineering techniques and of more precise assessments of hazards.

Research by Professor Roy Curtiss at the University of Alabama in the US, for example, has confirmed that the K-12 strain of *Escherichia coli*

Above: view of *E. coli* by scanning electron microscope; right: researchers working in a high containment laboratory

NIN

most commonly used in present recombinant DNA research is unable to survive in the human intestine like normal strains, and is thus very unlikely to cause an epidemic if it escaped from the laboratory.

This research has also led to the development of a "disabled" strain X-1776 which has already been passed by GMAG for some high-risk experiments. And it is widely expected that the successful development of a host-vector system using another "disabled" strain of *E. coli* with equally "safe" properties will be announced soon in the UK.

Such developments are already encouraging a certain relaxation of physical containment levels, in particular since the greater the biological safety of the organism, the lower the necessary degree of containment. In the US, for example, the National Institutes of Health published last summer proposed revisions to the guidelines first issued in June 1976. The new draft guidelines, which were publicly debated in Washington just before Christmas, and have already aroused considerable opposition from environmentalist groups such as Friends of the Earth, involve a considerable reduction in the containment levels for certain widely-used experiments.

Perhaps the most controversial proposal is to reduce the required physical containment level for experiments using recombinant DNA from mammals other than primates from P3 to P2; in practice this means that experiments using, say, mouse DNA which under the current regulations require purpose-built facilities, could be carried out on an open laboratory bench with a few relatively minor adaptations.

At present it is uncertain whether this particular proposal will be accepted (although others, such as a revised system defining physical containment requirements, probably will). Certainly many British scientists feel that, in the present state of knowledge, this may be relaxing things a little too far, at least for "shot-gun" experiments using unpurified DNA.

Yet the main concern about proposed revised guidelines is not so much their scientific content, but the fact that, if adopted, serious discrepancy between British and American laboratory practices could result, with potentially embarrassing consequences.

It could, for example, be cheaper to send a research worker to the US to carry out a set of experiments requiring little more than a conventionally-equipped laboratory bench, than to instal—or even hire—facilities providing the higher physical containment levels required to carry out the same experiment in the UK.

Such embarrassment is likely to be reinforced if other European countries, most of which have so far followed the British guidelines as suggested by the Williams Committee in 1976, decide to break ranks and, in line with the US, introduce significantly lower containment levels (as the French are, indeed, now proposing to do).

If, for example, Germany decides to introduce less stringent guidelines, British scientists working at the European Molecular Biology Laboratory at Heidelberg, which operates under German laws, may find they are permitted to carry out experiments which they are unable to do at home.

In such a situation, GMAG could find itself caught in a more difficult dilemma than that which it has already faced over confidentiality. For while responding—reasonably—to demands from scientists to rationalise containment levels, public confidence requires that it must not be seen to be responding to outside, and particularly industrial, pressure.

The members of GMAG are conscious that if they impose too harsh a set of restrictions on industrial research programmes as compared with other countries, companies will merely transfer their research programmes—and their revenue-earning potential—elsewhere; "and we don't want a repeat of the penicillin story", according to one GMAG member.

However, the Williams Report, which itself followed the public discussions generated by the Ashby report of 1975 and received evidence from a wide range of bodies, is still less than two years old. Any major attempt to re-draft its proposals at this stage is likely to be seen as premature, if not by scientists at least by the public, to whom some of the more fanciful possibilities (and dangers) of genetic engineering have only recently come home.

Indeed, it is one of GMAG's strengths that, through the trade union and "lay" representatives, it is able to take public concern directly into consideration (thus avoiding the major confrontations between scientists and the public that have, for example, occurred in the US).

Yet as the pressures on GMAG increase, so the tensions between its constituent parts may become more difficult to control. Such tensions arise partly from the ambiguous nature of GMAG itself, seen by some as an unfortunate, if necessary, part of scientific bureaucracy, and by others—including the trade unionists—as a successful model of public participation in research policy, with potential applications in other areas.

Disagreement over how to handle the confidentiality issue has already

brought these tensions to the surface. And while there is little criticism of the behaviour of the trade union representatives on scientific aspects of GMAG's work, they have already been accused of trying to make "political" points out of issues such as the future of the Ministry of Defence's Microbiological Research Establishment at Porton Down (part of which is likely to be transferred to the Department of Health and Social Security for carrying out top risk experiments requiring Category IV containment levels).

The political temperature of the debate has been raised by the recent decision of the British Society for Social Responsibility in Science to set up a genetic engineering group. This has already attacked the "complacent" attitudes of many scientists towards the safety aspects of such work. And the BSSRS group also feels that safety guidelines should have the force of law.

These issues will also undoubtedly be aired at the public hearings into genetic engineering soon to be held by the House of Commons Select Committee on Science and Technology. Reactions to the decision to organise these hearings vary; some are wary of the effects that renewed public exposure will have, and of possible "anti-scientific feeling" on the committee, while the BSSRS group has, in contrast, given the decision enthusiastic support.

But there are a number of important issues in need of attention. One of these is the make-up of GMAG itself, whose members are due to be reappointed at the end of 1978. Many would like to see more scientists on the group, particularly experts in fields of research not adequately covered at the moment. And there is still a residual unhappiness that although GMAG has two ASTMS representatives, there is no member of the Association of University Teachers acting in a representative capacity.

Another issue to which the Select Committee may give its attention is the intensive, quantitative study of the potential hazards of genetic engineering research. So far, despite an apparent commitment both in the US and the UK to the need for such work, little has yet been done by the scientific community actively to promote it.

GMAG is due to present its first annual report to Mrs Shirley Williams, Secretary of State for Education and Science, in a few weeks time. One thing is already clear: that GMAG's role is likely to become both more important and more difficult. As Sir Gordon says: "If anything, our 'political' problems are not going to die out, they will increase; and not because anything is going wrong, but because it is in the nature of the animal." □

Austrian science journalists were warned

SIR,—As one of the people principally involved in disclosing the fraudulent activities of Schaden ('Austrian science minister attacks science journalists in fraud case' 24 November, page 292), I should like to point out that in 1973 I warned Austrian scientists and science journalists about the questionable 'discoveries' of Schaden and Celta. Unfortunately, as the Science Ministry's document demonstrates, this was to little avail.

The purpose of the document and the Ministry's previous interventions and warnings, was to protect the scientific community from public discredit on account of a charlatan's 'research'. It was also to serve as a constructive warning to scientific journalists not to take every apparent scientific 'break-through' at its face value.

If the Science Ministry's document lacks thoroughness, this will certainly be supplied by the court's records of the Schaden case.

Yours faithfully,

WILHELM GRIMBURG

A third world energy view

SIR,—Effective use of the world's finite cheap oil reserves to save time and effort deserves a broader discussion than that given by Alvin M. Weinberg (20 October, page 638). Efficiency of the conversion of energy into time saved is highly variable. To travel 15 miles, for large numbers of people, means walking in the tropical heat carrying luggage and taking, say 5 hours. To be lucky enough to have a small motorcycle (and do the journey in 30 minutes on 0.1 gallons of fuel) saves 45 gruelling man hours per gallon. To then change to a large car (and come back at 90 miles per hour using 1 gallon of fuel) will only save a further 0.37 man hours per gallon.

The assertion that "a free society allows each of us to make the choice" and "economics . . . integrates all these . . . judgments" means that the rich have the right to decide. But when availability of cheap oil begins to decrease these judgments will, no doubt, be re-evaluated, and those who make them now thus carry a heavy respon-

sibility. Surely they will be expected to justify their judgments when others reach the position where they could use oil but find that it has all been carelessly squandered to save milliseconds of millionaire's time per gallon.

Yours faithfully,

Desert rainfall

SIR,—J. L. Deaton (24 November, page 294) makes several statements concerning our article (19 May, page 192) with which we disagree. He claims, in particular, that "in no sense is the mean too large". There is, however, a well defined sense in which the mean of a positively skewed distribution (for example, precipitation) is "too large". Specifically, it may be desired that a statistic, to be taken as a measure of central tendency, has the property that either it represents the midpoint of the distribution (that is the median), or that it represents the value of the distribution which is most likely to occur (that is the mode). If the distribution is positively skewed, then the mean is larger than the values satisfying either of these properties.

Deaton also claims that the mean "is quite indicative of how much rain commonly falls in most regions—even Gao and Niamey." But the mean, at least in some sense, is not at all indicative of how much rain "commonly" falls in the Sahel. As an example, consider the Gao August precipitation data used in our article: only 4 of the 35 observations (11%) fall within 10% of the mean; 23 of the 35 observations (66%) fall below the mean; and the mode (or most 'common' value) is 80.0 mm, substantially less than the mean of 100.9 mm.

Deaton states that "there seems to be only a slight tendency for the degree of skewness to increase as the average amount of precipitation decreases". This statement contradicts the results of studies on this issue in the climatological literature (Arnold Court in *Climates of North America*. World Survey of Climatology 11, 212 (Elsevier, Amsterdam 1974)). While it is true that all precipitation distributions are at least slightly positively skewed, there is a marked tendency for the

degree of skewness to increase as the mean precipitation decreases.

Finally, Deaton asks for documentation of the observation that "recent weather tends to influence perceptions more heavily than earlier weather and wet spells more heavily than dry ones". The documentation for this statement is a quote from J. C. Caldwell "Rain-fall Statistics, Droughts, and Desertification in the Sahel," *Desertification*, 84 (Westview Press, Boulder, Colorado 1977).

IQ or intelligence type?

SIR,—The controversy over race and IQ is clouded by the lack of culturally neutral testing procedures. Who would we be to say that a community of blacks who tested slightly lower than comparable whites were not immeasurably superior in forms of mental ability not emphasised in the test procedures? A slight mean shift from one community to another would doubtless be given more weight than it deserves, and it would still be possible (if its Gaussian distribution was shallower) for the 'less endowed' community to provide more geniuses than its counterpart. Furthermore, the difference between the two means would certainly be less than that between any two members of either group that you might encounter in the street, but would this be taken into account by those with political motivations? Data may be used to substantiate whatever case and in an area like this the phenomenon could have serious consequences. The "compensatory advantages" Sir Andrew Huxley cites in his address to the British Association annual meeting would soon be seen as racially-discriminative favouritism, and is it really so likely that humane considerations would moderate the debate? We take scientific findings much less seriously than it is popular to imagine: the new evidence in fields such as psychokinesis, spoon-bending, E.S.P., and tobacco smoking has done little to alter the attitudes of those with convictions of convenience that contradict the specialist conclusions, and there are still

eminent scientists who refuse to accept evolutionary theory and rely instead on more metaphysical alternatives. Scientific findings do not alter human belief so readily.

Huxley says that it is a characteristic of research that its outcome is not known in advance. That is so: but it is a presupposition of outcome that often motivates research, which may bias its interpretation, and which makes it possible that results will not alter preconceptions. In the correspondence for the same issue in which Huxley's reply to *Nature's* earlier editorial on his address appears (29 September, page 366), C. J. Robbins subscribes to the widely-held view that science sets out to falsify theories through experimentation. As the pages of *Nature* show, this is rarely true; the commonest motivation in research might well be exactly the converse.

The concept of IQ itself is a simplistic parameter which assumes that cognitive, perceptual, deductive and mathematical abilities go hand in hand, whereas our selection of individuals (for employment, etc.) shows this cannot be the case. We accept that brilliant mathematicians may be absent-minded, that musicians may be hopeless fine artists, scientists poor communicators. Why then do we hear so little about what we might call intelligence type? Until we have evolved realistic codes of criteria for assessment that reconcile mental measurements with the realities of life I believe we should postpone spurious research into racially-determined IQ, and recognise it as being ill-founded and premature.

In my view this is the most objective manner in which one could admit the limitations of contemporary science, and the irrelevance of research findings to those determined to subscribe to their own beliefs; these two are topics that are ripe for research.

Yours faithfully,

Science Unit, Cardiff, Wales

Soviet genetics

SIR,—As far as I know, gerontologists have been wary, over the years, of passing opinions on human genetics and on human genetics programmes. I was therefore very interested to read the review by Dr Zhores Medvedev, a noted gerontologist, on the development of human genetics in the USSR since Lysenko ('Soviet genetics: new controversy', 28 July, page 285).

The review bears a title which is frightening for anyone knowing the history of genetics in that country. A new controversy is hardly needed at this stage. The international congress of genetics is due this year in Moscow

and even calling attention to controversy might cause unpredictable side effects. Fortunately, renewed anxiety for the fate of human genetics in the USSR seems premature at this stage; the review gives a brief account of the re-emergence of the discipline, and for the rest is an all-out attack on the retiring director of the Institute of General Genetics of the Academy of Sciences, Dr N. Dubinin.

Of those who reinstated human genetics in the USSR Medvedev writes: "all of them were void of real practical knowledge of human or medical genetics", and one is left to wonder how they happened to have the courage to do it. Furthermore, if those who only had knowledge of drosophila genetics, of radiation, rodents, cytology and theoretical human genetics can be criticised for their contribution what can a gerontologist say about human genetics; in what position is he to pass value judgements?

Dr Medvedev, although he does not say so, must have participated in the discussions, since he says they were peaceful, albeit not very productive. Again one wonders how the new Institute of Medical Genetics was established as an outcome of such a lack of productivity.

One cannot help noticing the amount of negative emphasis put by Dr Medvedev on an action which tended to reconstruct human genetics. It is my opinion that, since these negative emphases diminish the whole operation, he should produce the evidence on which they are based. What, for example, is the evidence that D. K. Beliaev had been appointed in 1976 president of the 1978 Congress? This is puzzling, because Beliaev is general secretary, and Tsitsin (wheat hybrids at Lysenko's time) is president.

The part of the review which is devoted to Dubinin is less important. Dubinin, as others, went through the bitter years of the Soviet geneticists and survived. At present, he seems to have developed his own personal views on the inheritance of human abilities; these views are questionable but since they have been publicly castigated, they are not official views which might endanger those not sharing them. It seems arbitrary to associate them with a controversy which might harm human genetics; he is entitled to his opinions, no less than Medvedev to his own and I to mine. So far as some of Dubinin's work on human genetics is concerned, and so far as I can read, he has recently used erroneous techniques in the study of multivariation in quantitative traits in man. However, it might well be that, as director, he signs work from his institute which might be beyond the capacity of his technical

judgment (for example *Dokl. Akad. Nauk.* 230, 4: 957-960, 1976).

I believe that the most contradictory aspect of Medvedev's review is that Dubinin is turning against the programme he helped to start a short time ago. I believe that the accusation Medvedev makes, that "Dubinin is working hard to suppress by all possible means the development of genuine research in the field of human genetics in the USSR", and which amounts to public condemnation, is so important, that Medvedev is bound to produce evidence for it. It would be sad for those who have helped in the reconstruction, even for those who have given a minimal contribution, if attempts to create new conflicts hinder development. Human genetics is a hot science to handle: it seems useless to make it even hotter. After all, state and interstate budgets for human genetics can be cut easily, both east and west of Greenwich.

The Messinian salinity crisis

SIR,—Lines in reply to an anonymous critic (20 October, page 646).

When composing lyric verse

Be it critical or worse

It is wise to be quite certain of one's ground,

And not to call absurd

Quite a harmless little word

Lest its meaning be not simple but profound.

Crises evaporitic

Irritate our nameless critic

Rightly so, had we but meant what he implied,

But salinity increased

Until crisis point was reached

Whereupon the fauna disappeared or died.

Oh, 'tis pity I declare

That whatever we prepare

And however clear the message that we send,

There are always colleagues who

Having little else to do

Criticise us when they do not comprehend.

N.B.—The term 'Salinity Crisis' was, I believe, coined by Ruggieri (Systematics Association Publication No. 7 (eds Adams, C. G. and Ager, D. V.), 283-290 (London, 1967)) and referred to the apparent extinction of the marine faunas of the western Mediterranean in Messinian times.

Your faithfully,

C. G. ADAMS

news and views

T cell hybrids: shortcut or dead end?

from F. Melchers

THREE years ago everybody believed that normal lymphocytes could not be fused with malignant lymphocytes in culture. Then Köhler and Milstein (*Nature* **256**, 495; 1975) successfully fused an immunoglobulin-secreting myeloma with normal B lymphocytes which secreted antibodies specific for sheep red cells. This encouraged many laboratories to produce fused B cell lines secreting antibodies with a variety of required specificities (see *News and Views* **266**, 495; 1977). These 'hybridomas' (or Köhler lines perhaps?) represent a breakthrough in immunological research. Effector functions of clones of particular lymphocytes, in this case specific antibody production by B cells, can be made immortal. Consequently the clones can be grown up in large scale preparations that will allow structural and functional analyses of the clonal products.

It is difficult to say how this success came about after all the failures. Improvements in tissue culture techniques and selection of suitable malignant cell lines for fusion certainly helped. Köhler and Milstein recognised (*Somatic Cell Genet.* **3**, 303; 1977) that malignant and normal lymphocytes used in the fusion had to be at a comparable stage of differentiation. As a simple rule B cells, but not T cells, could fuse with B myelomas.

Once the ice had been broken everybody was eager to try similarly to fuse normal T lymphocytes and their malignant counterparts. This has now been achieved in several laboratories (Goldby *et al.* *Nature* **267**, 707; 1977; Hämmerling *Eur. J. Immun.* **7**, 743; 1977; Köhler *et al.* *Eur. J. Immun.* **7**, 758; 1977). For these fusions a suitable malignant cell line with T lymphocytic markers had to be found. Robert Hyman from the Salk Institute in La Jolla provided it in the T lymphoma BW5147. Fusion between normal T cells and this cell line was demonstrated by the codominant expression of genetic markers which

differ in the two cells, such as histocompatibility antigens, the T-cell specific Thy-1 marker and isomeric forms of the enzyme glucose-6-phosphate isomerase.

The ultimate aim of these fusions, however, is to preserve the effector functions of the parent T lymphocytes and thereby create cell lines with which the different effector functions of T lymphocytes could be elucidated. This, however, has proved less easy than had been anticipated. None of the T-cell hybridomas has so far revealed any effector function expected for normal activated T cells. There might be several reasons for this failure: the genome of the tumour cell might suppress the expression of the effector functions of the normal T cells; the chromosomes of the normal cells carrying genes for these effector functions might be lost after fusion and during growth of the T hybridomas. It is also possible that we are unable at present to fuse normal, activated T lymphocytes expressing a given effector function with T lymphoma cells or to assay for T cell effector functions *in vitro* when these functions are provided by individual clones of T cell hybridomas.

Three major immunological functions are attributed to T lymphocytes: help and suppression of B cell growth and maturation and killing of target cells. All three functions are thought to be initiated through clonal selection of specific T cells by antigen, resulting in the growth and differentiation of clones of antigen-specific T cells.

How, then, are these functions to be detected '*in vitro*'? First and most important, no single cellular assay exists for any T cell function as it does for immunoglobulin-secreting B cells in the form of Jerne's haemolytic plaque assay. Killer cells are most often monitored by ⁵¹Cr-release by labelled target cells. This method has recently been improved so that between 50 and 250 specific killer cells can now be detected in one culture, allowing *in vitro* analysis of the frequencies of target cell-specific killer T cell clones

(Teh *et al.* *J. Immun.* **118**, 1057; 1977). The general cytolytic activity, independent of the antigen-binding step, of killer to target cell can also be measured with a ⁵¹Cr-release assay. Killer and target cells in this non-specific assay are brought into close contact by agglutinins which act as a glue (Forman & Möller *J. exp. Med.* **138**, 672; 1973; Bevan *et al.* *Eur. J. Immun.* **6**, 150; 1976). The antigen-nonspecific cytolysis which occurs when the killer and target cells are in close contact, is precisely what seems to make successful fusions between activated killer T cells and a malignant T cell line impossible, since fusion necessarily involves close contact of the two cells to be fused. Köhler and his collaborators (*Eur. J. Immun. op. cit.*) have now shown that the close contact of activated T killer cells with the BW5147 T lymphoma line during the fusion reaction kills the T lymphoma cells and thereby prevents probably all killer cells, regardless of their target specificity, from becoming immortal. There is little hope of this nonspecific killing mechanism ever being inactivated during the fusion reaction, allowing the establishment of T cell hybridomas with killer activity.

In vitro assays for T cell help or suppression of B cells seem even less sensitive than killer assays. Furthermore, there still exists considerable controversy over the mechanism of T cell dependent B cell triggering (at its height in *Transplant. Rev.* **23**, 1975). Depending on which immunologist one talks to, quite different structures and actions are expected from the products of a T cell hybridoma. Many immunologists believe that T cells produce antigen-specific factors, which for a long time were thought to be immunoglobulin. This now seems less likely. Some people think that such factors carry Ia antigen, but others cannot find these Ia antigens on their factor preparations. Many also believe that these antigen-specific T cell factors in some way induce B cell growth and maturation to immunoglobulin secretion and are therefore mitogenic for B cells.

This all argues for soluble products effecting T cell help and suppression, but not everyone is yet convinced that cell-cell contact can be ruled out as the basis of the physiological action of T-B collaboration. Conceptual confusion prevails in a situation in which convincing experiments are still somewhat scarce.

The chances of finding a T-cell hybridoma which produces helper factor for a given antigen are indeed very low—approximately 1 in 10^4 for the antigen sheep red cells (Lefkovits & Waldmann *Immunology* **32**, 915; 1977). No wonder then that the few T hybridomas which have been tested so far for such antigen-specific helper functions do not produce them (Köhler *et al. op. cit.*). If these factors are mitogenic for B cells it might be predicted that, at higher concentrations, they could polyclonally activate all B cells which are receptive to the mitogenic principle of the factor regardless of the specificity of these B cells for the hapten. Assays for B cell mitogeni-

city have become very sensitive (Andersson *et al. Cell* **10**, 27; 1977) and such assay systems might be useful to detect growth-inducing properties of factors produced by T cell hybridomas, or even by T lymphomas.

However, one may still hope that T cell hybridomas will open up a new way to an understanding of normal T cell effector functions of help and suppression and their molecular mechanisms of action. Binding of antigen to T cell hybridomas or to molecules released by them seems one simple first step. Selection of T lymphoma lines which display nonspecific helper or suppressor activities with normal B cells, may also help—keeping in mind the 'rule' that cells at comparable stages of differentiation might fuse more easily with each other. Beyond that immunologists will have to replace ideology by scientific knowledge, obtained through better assays, so that they can detect what may be present in, on, or released by, T cell hybridomas. □

Maeyer-Guignard *et al. Proc. natn. Acad. Sci. U.S.A.* **69**, 1203; 1972). The assay can be made quantitative (Kronenberg & Friedman, *J. gen. Virol.* **27**, 225; 1975; Greene *et al.*, this issue of *Nature*, page 81). Second, both mouse and human interferon mRNAs have been translated in cell-free systems, mouse interferon mRNA in the wheat germ system (Thang *et al. Proc. natn. Acad. Sci. U.S.A.* **72**, 3975; 1975) and human interferon mRNA in cell-free extracts from mouse ascites cells, rabbit reticulocytes and wheat germ (Pestka *et al. Proc. natn. Acad. Sci. U.S.A.* **72**, 3898; 1975; Reynolds *et al. Proc. natn. Acad. Sci. U.S.A.* **72**, 4881; 1975; Raj & Pitha *Proc. natn. Acad. Sci. U.S.A.* **74**, 1483; 1977). Third, human interferon mRNAs have also been translated after injection into *Xenopus* oocytes (Raj & Pitha, *op. cit.*; Cavalieri *et al. Proc. natn. Acad. Sci. U.S.A.* **74**, 3287; 1977; Sehgal *et al. Proc. natn. Acad. Sci. U.S.A.* **74**, 3409; 1977), and both the cell-free assay and the oocyte assay can also be made quantitative. The products of these translation systems have been characterised as interferon using species and antigenic specificities, and sometimes also by showing the product to have the expected molecular weight. Use of the *Xenopus* oocytes showed that injection of polyadenylated RNAs from induced fibroblast and lymphoblastoid cells yielded fibroblast and leukocyte interferons respectively, demonstrating that human cells can produce two different translatable mRNAs and probably contain two genes for interferon, coding for polypeptides differing in primary sequence.

What has been learnt about the control of interferon formation using these translation systems? It is well established that the interferon mRNA is found in the polyadenylated RNA fractions, although there has been a report of activity also being associated with non-polyadenylated material (Montagnier *et al. Biochem. biophys. Res. Commun.* **59**, 1031; 1974). No translatable RNA has been found in uninduced cells, and therefore induction is accompanied by a rapid increase in the amounts of translatable RNA. Thus the switch-on of interferon synthesis requires new transcription; the alternative explanation that translatable RNA is processed from a pre-existing RNA species is ruled out because of the well known inhibitory effect of actinomycin on interferon production. Two groups (Sehgal *et al. op. cit.*; Greene *et al. op. cit.*) have also shown that interferon mRNA is undetectable 6–8 h after induction with double-stranded RNA. This suggests that the switch-off of interferon production is due to cessation of mRNA

Translation of interferon messenger RNA *in vivo* and *in vitro*

from Derek Burke and John Morser

INTERFERONS are induced when a large variety of animal cells are treated with viruses or double-stranded polyribonucleotides. Cells which, before induction, were producing no detectable interferon, will produce up to 10^5 reference research units of interferon per 10^6 cells in the 24 hours after induction. Cells that have been induced are switched-off a few hours later. A second dose of interferon inducer does not lead to a second yield of interferon; the cells are described as hyporesponsive. Production of interferon can also be modulated in other ways; pretreatment of cells with small amounts of the homologous interferon before addition of an interferon inducer often increases the yield, a phenomenon termed 'priming'. Certain metabolic inhibitors added after induction with a double-stranded RNA can have a similar effect, a phenomenon called super-induction. Since purified interferon has a high specific activity (approaching 10^6 units per mg protein) and since the bioassay can easily detect 10 units of interferon, the production of very small amounts of interferon can be measured. Interferons are usually species-specific: interferon made in

mouse cells is inactive on human cells and *vice versa*. But even within the interferons produced by one species, there may be heterogeneity, for there are at least three different types of human interferon, which are distinguished by the type of cell in which they are formed: fibroblast interferon, leukocyte interferon and immune (type II) interferon produced when lymphocytes are treated with mitogens. Lymphoblastoid cells produce mainly the leukocyte type. These three interferons are antigenically distinct and have different physical and biological properties. The ease of detecting small amounts of interferon, the tight control of interferon production, and the existence of several different human interferons all make the interferon production system attractive for exploring the control of inducible proteins in eukaryotes. With the development of systems for translating interferon mRNA *in vitro* interesting answers about the control are beginning to emerge.

Three techniques have been developed for translating an interferon mRNA *in vitro*. The first involves application of RNA extracted from interferon-producing cells to heterologous cells with production of interferon characteristic of the cells from which the RNA was extracted (De

synthesis as well as to its inactivation.

The levels of interferon mRNA have also been measured in normal and superinduced cells, in order to determine whether the increased interferon production is due to a corresponding increase in the amount of mRNA. Raj and Pitha (*op. cit.*) found that the levels of interferon mRNA at 6 h after induction were very much higher in superinduced cells than in normal cells when the wheat germ system was used, but that there was little difference when the *Xenopus* oocyte system was used. In contrast Sehgal *et al.* (*op. cit.*) found the levels of mRNA were higher in superinduced cells using the oocyte system but they could not obtain translation of the same mRNA preparations in cell-free systems. Although there are differences between these two reports, both groups agree that the increased level of interferon production in superinduction is not due to the synthesis of new interferon mRNA, but is due to a change in the fate of the mRNA. Pitha and

Raj (*op. cit.*) suggest that similar levels of interferon mRNA are produced in normally induced and superinduced cells, but that the majority of the mRNA is in an inactive form in normally induced cells. They further suggest that superinduction is due to a modification of this RNA, which can also take place in *Xenopus* oocytes, but not in the wheat germ translation system.

However, Sehgal *et al.* (*op. cit.*) suggest that in normal cells mRNA is being degraded or inactivated but that superinduction prevents this process, through the action of a repressor gene. Although there are clearly still some difficulties in correlating the *in vivo* and the *in vitro* results, the experiments have already led to models of the control of interferon synthesis which can be tested. In the longer term, more detailed analysis will require other approaches, for example the use of nucleic acid hybridisation techniques to measure the amount of interferon mRNA directly. □

At that time, a number of endemic African forms moved out to occupy the Eurasian land mass. Hominoids of the *Proconsul* type were apparently among these emigrants and they rapidly spread very widely.

Recent work in Hungary (Kretzoi *Nature* **257**, 578; 1975), Greece (de Bonis *et al. Cr. Séanc. hebdom. Acad. Sci. Paris Ser. D.* **281**, 379; 1975; **284**, 1393; 1977) Spain (Crusafont-Pairo & Golpe-Posse, *J. hum. Evol.* **2**, 17; 1973), Turkey (Tekkaya *Bull. Min. Res. Exp. Ankara* **83**, 148; 1974; Andrews & Tobien, *Nature* **268**, 699; 1977) and on the Potwar Plateau has greatly increased our knowledge of this hominoid radiation.

It is now apparent that at least three genera, *Sivapithecus*, *Ramapithecus* and *Gigantopithecus*, may be recognised in deposits reflecting the more open woodland habitats of that time. These three genera share a complex of characters which may reflect a dietary adaptation to the harder or coarser foods of such environments. These features include thick enamel on the teeth, cheek teeth which were large in relation to body size and a mandible which was heavier and thicker than that of their more ape-like contemporaries.

From our point of view, the most interesting of these woodland-adapted genera is *Ramapithecus*. This genus is considered by many to be the earliest known member of the Hominidae, the family to which man and his phylogenetic ancestors belong. Indeed, as Pilbeam points out, unworn cheek teeth of this middle Miocene form very closely resemble those of later hominids such as *Australopithecus* and *Homo*. The earliest known member of this genus, and the family Hominidae, was recovered at Fort Ternan, Kenya just below a level dated with potassium/argon to 14 Myr BP. It has recently been suggested that an even earlier member of the genus may occur at Pasalar, Turkey (Andrews & Tobien *op. cit.*). However, the date of these Turkish deposits is based on faunal remains and it must be pointed out that not all elements of the Pasalar fauna confirm the suggested date of 15 Myr. For example, the bovid taxon *Prostrepsiceros rotundicornis* may occur at Pasalar but it does not appear elsewhere in Europe until about 10 Myr ago. If this species does indeed occur at Pasalar then a date for these deposits of 15 Myr must be treated with extreme caution.

However, the suggestion by Andrews and Tobien of a non-African origin for the hominids is an intriguing one. The genus *Ramapithecus* is known only from a single site in the whole of Africa and it is there found in association with a fauna that has many im-

Hominoid habitat shifts in the Miocene

from G. E. Kennedy

THE middle Miocene was a time of widespread environmental shifts which resulted in profound changes in many faunal groups. The tropical and subtropical forests of the earlier Cenozoic had provided large and virtually unbroken tracts of lush, protective habitat for many animals. But by the middle Miocene, around 9–14 Myr ago, a general cooling trend, coupled with tectonic and mountain building activity, had fragmented these forests into smaller, discontinuous habitat areas. With the decline of this habitat space, many animals moved from their long-occupied forest niches into the newly expanding, more open woodland areas. Among the Miocene faunal groups which made a shift from forest to open woodland were some groups of the Hominoidea—that primate super-family which contains apes and man, both living and fossil. In a recent issue of *Nature* (**270**, 684, 689; 1977) Pilbeam *et al.* report on some middle Miocene hominoids from the Potwar Plateau, in the Punjab Province of Pakistan which had made such a shift.

Hominoids of Miocene age have been known to palaeontologists since 1856. Their diversity, both morphological and geographical, led to a pro-

liferation of taxa which made the group unwieldy, if not incomprehensible, even to specialists. A revision of their taxonomy in 1965 (Simons & Pilbeam, *Folia primat.* **3**, 81) was a welcome move in increasing understanding of the interrelationships of this group, which may contain the ancestors of living gorillas, chimps and man.

However, Pilbeam's work and the work of other primate palaeontologists now indicates that the elegant simplicity of that taxonomic scheme may have underestimated the vigour of the adaptive radiation of the middle Miocene hominoids. Since that revision several new genera have been proposed and more recently it has been suggested that two genera, previously sunk to sub-generic level, should now be reinstated as full genera. One of these, *Proconsul*, was an African early Miocene forest-living form, apparently at or near the ancestry of most later hominoids. Pilbeam now suggests that the other genus, *Sivapithecus*, was among the hominoids which made a habitat shift during the middle Miocene. A similar suggestion has recently been made by Andrews in a paper given at the VI International Primatological Congress, at Cambridge, 1976.

The opportunity to make this shift was enhanced when the long geographical isolation of the African continent ended about 16–17 Myr ago.

G. E. Kennedy is in the Department of Anthropology, University of California at Los Angeles.

migrant, Eurasian elements. The geographical origins of the Hominidae should be a fascinating area of research in the coming years.

The environment in which the early hominids lived is also an intriguing area of study. Many theoretical discussions of hominid origins have been based on the development of an adaptive complex which emerged in response to pressures from savannah or grassland environments. However, as considerable recent research has indicated, grassland environments were not occupied by the earliest hominids and were, in fact, only entered by this group relatively recently. Therefore, occupation of the savannahs cannot have been the 'initial kick' which led to the emergence of the family Hominidae. Savannah adaptations may well have been important in the course of later hominid evolution, particularly in the Plio-Pleistocene radiation, but they cannot have been an initiating factor. Moreover, it is of interest and of uncertain significance that not all ramapithecines have been found in woodland deposits. In two areas, at Rudabanya, Hungary (Kretzoi *Nature op. cit.*), and, at Keiyuan, south China (Chow *J. paleont. Soc. Ind.* **3**, 123; 1958) this form has been found in lignite deposits indicative of very moist, heavily vegetated conditions.

Clearly, the adaptive radiation of the middle Miocene hominoids was very complex. The human ancestors, rather than showing a unique and singular pattern of evolution were, in fact, part of a much broader process.

'Cardiac' RNA

from Jonathan Slack

It has long been realised by developmental biologists that the formation of ordered patterns of cell types during embryonic development requires the existence of interactions between different parts of the early embryo. The chemical nature of the putative signals has been a tantalising mystery ever since the abortive 'gold rush' to isolate Spemann's organiser during the 1930s. To the biochemically minded, informational macromolecules such as RNA present themselves as obvious candidates, while to the adherents of 'gradient' models they seem to be a red herring, and the signals are generally thought to be small molecules or ions which unleash complex responses

from the target cells.

Two recent papers from A. K. Deshpande and M. A. Q. Siddiqui (*Dev Biol.* **58**, 230; 1977; *J. biol. Chem.* **252**, 6521; 1977) make up an interesting contribution to this debate. They have isolated a specific fraction of RNA which causes a specific type of cell differentiation in explants from early chick embryos. At the stage concerned (Hamburger and Hamilton's stage 4), a chick embryo consists of two layers of cells: the epiblast above and the hypoblast below. Joining these layers down the centre is a mass of cells called the primitive streak through which cells are migrating to form a mesodermal layer in between the other two. At the front end of the primitive streak is a condensation of cells called Hensen's node, which is supposed to be the 'organising centre' for the formation of the general body plan.

Deshpande and Siddiqui have isolated their RNA species from the hearts of quite advanced (16 day) embryos. It is about 7S (200 nucleotides) in size and contains a sequence of poly(A). When the 'post nodal piece', roughly the posterior third of the early embryo, is treated with this RNA *in vitro*, it differentiates into cardiac muscle tissue.

What distinguishes this result from claims of this type in the past is the careful characterisation of the response and the large number of controls. The positive cases show beating movements and contain myofibrils (electron microscopy), actin and myosin (gels), glycogen granules (histochemistry) and acetylcholinesterase (assay) in quantities appropriate to cardiac muscle cells. The posterior explants do not form cardiac tissue or anything much else when cultivated on their own, nor when treated with RNA from a variety of other sources, or with synthetic polynucleotides. However, it is not yet proved that the 7S RNA enters the cells in an intact form.

The intriguing thing about this result is that it makes little sense in terms of early development. The fate of the post nodal piece in normal development is to form the posterior axial structures—notochord and somites. When cultured on its own *in vitro* it does not differentiate at all, and when cultured in the presence of Hensen's node it will differentiate into axial structures (Butros *J. exp. Zool.* **149**, 1; 1962). It seems probable that this region is competent to form heart since the determination of the overall body plan is still going on at this early stage and classical work showed that quite an extensive lateral area would differentiate into heart when cultured *in ovo* on the chorioallantoic membrane (Rawles *J. exp. Zool.* **72**, 271; 1936). But according to our present ideas about pattern formation the position of

the heart rudiment should be specified by two distinct signals. This is because the paired rudiments are situated in a two-dimensional sheet of cells and located symmetrically on either side of the axis. There is no particular reason why any factor involved in these early signals should be present in 16-d heart at all. Significantly enough, the authors show that brain, liver and kidney RNA are all inactive, both in stimulating heart differentiation and in stimulating differentiation of their own cell types.

The 7S RNA itself does not seem to be a mRNA even though it contains a poly(A) sequence, since it cannot be translated *in vitro* and actually inhibits the translation of purified messengers in cell free systems. It will be most interesting to see whether this species exists in the early as well as the late embryo, for if it has a role in normal development it should be possible to find it there. □

First interstellar NO bond

from Graham Richards

THE list of interstellar molecules grows longer and longer and many large polyatomic systems have been positively identified with still more postulated. Despite this, NO bonds have been conspicuously absent from the lists and NO itself has been the subject of many unsuccessful searches. Now with the detection of HNO by Ulrich, Hollis and Snyder (*Astrophys. J.* **217**, L105; 1977) this anomaly in the chemistry of interstellar molecules may be removed.

The observations were made in March, 1977 with the 36-foot radiotelescope of the National Radio Astronomy Observatory. The single line ascribed to HNO was detected in emission from the sources known to astronomers as SgrB2 and NGC2024. In general it is difficult to identify a new molecular species positively on the basis of a single spectral line but in this case very accurate laboratory frequencies are available (Saito & Takagi *J. molec. Spectrosc.* **47**, 99; 1973). Further transitions of HNO may require observations at millimetre wavelengths.

Comparison with the very similar molecule HCO suggests an abundance ratio of carbon to nitrogen of about 1.4 in the same interstellar clouds, which conforms with cosmic abundance estimates. The chemical simi-

Jonathan Slack is a developmental biologist working at the ICRF Laboratories, Mill Hill, London.

Graham Richards is a lecturer in the Physical Chemistry Laboratory of Oxford University.

larities between HCO and HNO in all probability do not extend as far as the formation mechanisms. The formation of HCO is likely to depend on the availability of ionised carbon in moderate-density clouds. Ionised nitrogen may not be so readily available, so that the best suggestions for HNO formation come from Dalgarno

followed by

the initial NH_3^+ being derivable either from neutral nitrogen

or from the ion, N^+ , and unionised hydrogen molecules.

The letter in the *Astrophysical Journal* also reports a new unidentified line at a frequency of 81,505 MHz which may be a weak maser and observations of previously detected transitions of ketene (H_2CCO), dimethyl ether (CH_3OCH_3) and cyanoacetylene (HCCCN). A further unidentified line previously reported by Turner (*Astrophys. J. Lett.* **213**, L75; 1977) was also observed and ascribed to thioformaldehyde (H_2CS) or cyanoacetylene ($\text{HC}_2^{13}\text{CN}$).

The ambiguous identification, the unidentified line and above all the detection of an interstellar NO bond will all provide spurs for theoreticians to perform accurate calculations, spectroscopists to measure frequencies as well as encouragement for radio-astronomers to confirm and extend this study, perhaps once more searching for nitric oxide in interstellar regions.

Hydrothermal waters and heat flow

from Peter J. Smith

THE heat flowing outwards through the oceanic crust reaches the Earth's surface in three ways—by conduction, convection and radiation from the mantle and core, by conduction from radioactive sources in the crust itself, and by direct transport in the hot mantle material which rises at active oceanic ridges to form new lithosphere. Of the three, the most important is the last; indeed, more than 50% of the Earth's heat loss (that is, from oceanic and continental regions combined) takes place at oceanic ridges alone. With the possible exception of the few

Speed of light and relativity

from P. E. Hodgson

EINSTEIN'S special theory of relativity is based on two postulates—first that the laws of physics that hold in one coordinate frame also hold in any other coordinate frame moving with uniform velocity with respect to it, and second that the speed of light is independent of the velocity of the source. From these two postulates the theory of relativity can be derived.

The second of these two postulates can be tested experimentally and this has already been done in several ways. Among the most accurate is the study of gamma rays emitted from the decay of relativistic uncharged pions produced in very energetic nucleon-nucleon collisions. In one of these measurements the pions had an energy of 6 GeV and thus a velocity very nearly that of light, so that if the velocity of the source is added to that of the light, the gamma rays from their decay would have nearly twice the velocity of light, whereas if the velocities do not add the velocity is just c . There is thus nearly a factor of two between the velocities expected on the two possibilities, and this can be measured accurately by a time-of-flight method. If the result is expressed by saying that the measured velocity is

$$c' = c + kv$$

where k is a constant and v the velocity of the source, then the two possibilities correspond to $k = 0$ and $k = 1$. The measurements showed that k is smaller than 10^{-4} , which confirms the second postulate to high accuracy.

It is, however, always interesting to see if such an important result can be checked to even higher accuracy, and this has recently been done by Kenneth Brecher of the Center for Space Research at Massachusetts Institute of Technology (*Phys. Rev. Lett.* **39**, 1051; 1977). He made use of the regularly pulsing X-ray sources in binary star systems. Since in a binary star one component is orbiting round the other, if the system is observed in the plane of the orbit, for part of the period one star appears to be moving towards us and the other away from us, and the opposite happens half a

period later. If the velocity of the source is added to that of the light then we would not see two stars rotating around each other but instead would see complicated effects depending on the distance of the stars. In particular we would not see them continuously: they would appear and disappear as the various beams from the stars in different positions overtake one another as a result of their different velocities.

This method of confirming that the velocity of light is independent of that of the source was suggested long ago, but for light in the visible region it suffers from the objection that the radiation from a distant star is scattered as it goes through the intervening interstellar matter, and is then replaced by reradiated fields produced by the dipoles of the medium. This wave is then propagated with the phase velocity of the medium. Calculations show that for light in the visible region the characteristic length for the extinction of the original radiation is about two light years, which is less than the distance of the nearest star.

This objection does not apply to the 70 keV X rays emitted from some binary star systems, as they are much more penetrating and the interstellar extinction is negligible. Such stars thus provide a very sensitive way of testing the second postulate.

Brecher applied this method to three binary X-ray sources, and determined their distances, orbital periods, and Doppler velocities. A small but finite value of the constant k would affect the eclipse times and the apparent eccentricity of the orbit, and so measurements of these quantities enable upper limits to be set to k . A careful analysis of the results of the measurements showed that for one of the stars k is less than 2×10^{-9} , and for the other that it is less than 4×10^{-10} . These limits are much less than those set by the pion method. The second postulate is thus established to much greater accuracy than ever before.

P. E. Hodgson is a lecturer in Nuclear Physics in the University of Oxford.

local continental areas of high heat flow capable of providing geothermal power, oceanic ridges are therefore the most interesting of all the Earth's thermal features. They are also the most important in the sense that study of their thermal characteristics is capable in principle of throwing light on

some of the details of the plate tectonic processes which brought the heat to the surface in the first place.

Unfortunately, however, oceanic ridges are precisely those regions where heat flow measurement is most difficult and the results most uncertain. Conventional heat flow probes require for

their operation at least several metres of sediment, but the new lithosphere in ridge zones has had little time to develop a sediment cover. Measurement is therefore limited to the small isolated basins where sediment has begun to form, which are by definition not typical of the whole region. Moreover, the rugged ridge topography, which allows such sediment pools to grow and which is itself the product of variable thermal expansion, distorts the flow of heat and thus introduces geographical variations that are difficult to correct for. Small wonder, therefore, that heat flow data from ridges, though generally high as predicted by plate tectonics, are both highly scattered and subject to systematic errors which generally do not even permit calculation of a true mean value.

Nor is that all. Some of the systematic deviations (for example, the conspicuously low heat flow often found on ridge flanks) are so great that it is impossible to account for them either by topographic distortion or as the result of the accumulation of cold sediment. This has led several workers to suggest that an important influence on the distribution and variation of heat flow in the vicinity of oceanic ridges is hydrothermal circulation in the igneous upper crust—an idea put forward many years ago by Elder (in *Terrestrial Heat Flow*, edit. by Lee, W. H. K., American Geophysical Union, 1965) but promoted particularly vigorously in recent years by Lister (*Geophys. J.* **26**, 515; 1972 and subsequent articles). Lister's point is that heat advected from the crust by hydrothermal circulation which has open access to the ocean water will not be recorded by measurements limited to sediment pools. Average heat flow values obtained from ridge zones will therefore almost always be too low to be consistent with otherwise reasonable models of lithospheric accretion which ignore hydrothermics. Only when there is a complete sediment cover forming a continuous impermeable barrier between the igneous crust and the open ocean will the measured average heat flow begin to approach the true value of heat lost by the oceanic lithosphere.

The existence of hydrothermal circulation is now widely accepted, having been demonstrated to be the most likely explanation for the heat flow distributions revealed by several studies since 1972. A particularly striking confirmation of Lister's basic ideas, however, has now been reported by Davis and Lister (*J. geophys. Res.* **82**, 4845; 1977) who have obtained 104 heat flow results from a 110 km square area centred on the point where the Juan de

Fuca ridge meets the transform (Sovanco fracture zone) that offsets it from the Explorer ridge to the north. In the southern section of this area lies the northern end of the Juan de Fuca ridge with its young lithosphere (0–1.8 Myr old), whereas to the north of the fracture zone lies the older crust (3.3–3.6 Myr) which has spread from the Explorer ridge. In other words, the test area includes two quite distinct zones between which the effects of hydrothermal circulation, if any, may be compared.

Throughout the area as a whole the heat flow observations, made at roughly 10 km intervals, were highly variable, ranging from 1.4 to 15.9 $\mu\text{cal cm}^{-2} \text{s}^{-1}$ and having no obvious correlation with either topography or sediment cover. Moreover, this variability and lack of correlation were equally evident in eight measurements made specially at 2 km intervals. From this evidence alone it seems necessary to invoke hydrothermal circulation throughout the test area.

But the consequences of the circulation differ significantly between the two subzones. The overall picture is mirrored south of the fracture zone where the sediment distribution over the Juan de Fuca ridge and ridge flanks is intermittent and the sediment, where it exists at all, is thin. The heat flow variability is far too great to be explained solely in terms of topographic distortion or sedimentary accumulation. Where there is no sediment cover there must be open circulation between the hydrothermal waters in the igneous lithosphere and the ocean waters above, leading to an underestimate of the true heat flow by the actual measurements made in sedimentary areas. This is confirmed by plotting the measured mean heat flow against the reciprocal of the square root of the age of the lithosphere. The point thus produced lies way below the line derived from other Pacific heat flow provinces where there is no hydrothermal circulation.

North of the Sovanco fracture zone, on the other hand, the basement of the east flank of the Explorer ridge is completely covered with thick flat-lying sediment. The heat flow here is still variable, but rather less so than in the south of the test area; and there is now a distinct inverse correlation between heat flow and the corresponding sediment thickness. In principle, both the variability and the correlation could be explained either by topographic distortion (by which heat tends to converge towards areas where, because of topographic variations in the basement, the sediment is thinner and hence its insulating effect smaller) or by the cooling influence of sedimentary deposition. Indeed, the presence of the heat flow–sediment thickness correlation in par-

ticular points strongly towards just such explanations. Calculations show, however, that even in this zone these effects are insufficient.

So it is necessary to invoke hydrothermal circulation even though in this case there is a complete sediment cover. But this is not to say that the sediment cover has no effect. On the contrary, it prevents the hydrothermal waters in the igneous lithosphere venting to the ocean and thus eliminates the false measurement of heat flow inevitable in the case of the Juan de Fuca ridge zone. The measured average heat flow is thus the true heat flow; and this is confirmed by the fact that the former plots precisely on the Pacific heat flow–lithospheric age curve.

In summary, then, what Davis and Lister have shown, above all, is that artificially low values of measured heat flow are entirely consistent with the effects of hydrothermal circulation but that such circulation does not give rise to artificially low values of measured heat flow in all circumstances. Although hydrothermal circulation will always produce scatter of heat flow, a false average value will result only when the hydrothermal waters can vent to the ocean. Incidentally, such venting will, not surprisingly, also lead to a reduction in the average temperature of the hydrothermal waters themselves. Thus Davis and Lister estimate that temperatures at the top of the igneous crust range from 300 °C to 100 °C below the few well-sedimented sections of the Juan de Fuca ridge but from 200 °C to below 25 °C where there is no sediment cover. □

A hundred years ago

THE vessel was at this time in the neighbourhood of Terra del Fuego, about 140 miles from Magellan's Straits, when early in the morning it narrowly escaped collision with an island where no trace of land appeared on the charts. The vessel hove-to until daylight, when the captain proceeded with a boat's crew to the new island, which had gradually diminished in size since the first observation. Around the conical rocky mass the water was hissing, and although no smoke appeared, it was found to be too highly heated to permit of landing. The sinking continued slowly, until at eight o'clock the island was completely submerged, and an hour later the vessel passed over the spot where it had disappeared.

Prediction of protein structure from amino acid sequence

Michael J. E. Sternberg* & Janet M. Thornton*

In principle, it is possible to predict theoretically the three-dimensional structure of a protein from its amino acid sequence. Recently substantial progress towards this goal has been made by the use of simple models to represent protein conformation and interatomic interactions, together with the knowledge gained from analyses of known protein structures.

THE distinguishing feature of biological macromolecules, especially proteins, is their ability to adopt a unique three-dimensional structure (Fig. 1). It is this precise structure which is essential for recognition between different molecules in an organism and determines how they function. Thus knowledge of tertiary structure is vital for understanding biological function. Experimental evidence shows that all the information necessary for a protein to acquire its complex structure is stored in its linear amino acid sequence¹. Therefore theoretically one should be able to predict the conformation of a protein from a knowledge of sequence alone. Once a protein has been isolated, its sequence can almost always be determined. In contrast, structure determination is difficult and many proteins defy all attempts to obtain suitable crystals. Thus a successful prediction of three-dimensional structure, which implies a basic understanding of how structures are formed, would be an important step forward in molecular biology.

This review will examine the progress made in the prediction of protein structure from amino acid sequence over the last five years (for other reviews see refs 2–4). The major problem of prediction is that even a small protein, 50 amino acids, could adopt about 10^{50} conformations. How does one find the native structure amongst the myriad of alternatives? Recent progress towards a solution of this problem has been made by use of simple models to represent both the conformation and interatomic interactions of the protein, together with the knowledge gained from the increasing number of protein structures known.

Thermodynamics and kinetics of refolding

Many experiments^{1,5} have shown that most proteins can spontaneously refold in a biological environment, from a denatured state to their native conformation. Generally this is true for proteins with and without disulphide bridges and for both monomeric and multi-subunit proteins. These experiments led to the thermodynamic hypothesis¹, which states that the polypeptide chain folds so as to attain the conformation of lowest free energy. This hypothesis was modified in 1968 by Levinthal⁶, who also considered the kinetics of folding. *In vivo* proteins require between 10^{-1} and 10^3 seconds to fold up, and, since molecular rearrangements occur in about 10^{-13} s, a protein cannot possibly search all conformations ($> 10^{50}$) (ref. 7). Thus folding must be directed along pathways and the native structure will be at the minimum free energy of the kinetically accessible conformations. This local minimum need not necessarily correspond to the global minimum of free energy. To reduce the number of conformations searched it is thought that portions of the chain serve as

nucleation sites, around which the remainder of the protein folds. The α -helix and β -strand are possible sites. One suggestion for the pathway, called N-terminal folding, is that the polypeptide chain folds as it is being synthesised from its N-terminus⁸. Definitive experimental evidence on folding pathways has proved difficult to obtain. Studies on pancreatic trypsin inhibitor⁹ and hen egg white lysozyme¹⁰ suggest that at most there are only a limited number of folding pathways to the tertiary structure.

Energy calculations for atom–atom interactions

Theoretical predictions of structure have been influenced by both the thermodynamic and kinetic arguments. Initially the thermodynamic properties of polypeptide chains were considered. Liguori¹¹, Ramachandran¹² and their coworkers showed that the peptide unit can adopt only certain allowed conformations (Fig. 1d). By considering non-bonded interactions, they constructed ϕ – ψ plots which have subsequently been improved by semi-empirical energy calculations¹³ to predict preferred regions. There is good agreement between these preferred conformations and the observed distribution of ϕ , ψ angles. Recently energy calculations have been refined, either by choosing parameters to fit crystal structures¹⁴ or by performing complex molecular orbital calculations¹⁵.

It follows from the thermodynamic hypothesis, that by calculating the total free energy of a protein and finding the global minimum, it should be possible to predict the native structure. But at present this approach is not feasible. Not only is the computer time required excessive, but the energy surface is extremely complex with numerous minima. Consequently studies have been restricted to small sections of proteins and polypeptides¹⁶, and the refined calculations have only been valuable in the understanding of local conformation. The multi-minimum problem will probably be solved by finding the correct folding pathway. One step towards this goal would be the prediction of regular secondary structures from the sequence, since these structures may form the nucleation sites (see for example ref. 17).

Prediction of secondary structure

More than fifteen methods of predicting secondary structure from amino acid sequence have been proposed. (References are given to some of the more recent approaches: 18–27.) These predictions assume that local sequence determines local structure, which has been partially verified by the results. Usually only short-range interactions are considered, interactions between distant chain segments being ignored.

Broadly the methods can be divided into two categories. First, there are the statistical methods. In proteins of known sequence and structure, each residue is assigned to one class of secondary

Fig. 1 Protein Structure. The figure shows how the complex three-dimensional structure of a protein—(lactate dehydrogenase (LDH))—can be simplified for use in analysis and prediction. *a*, A stereo diagram of the main chain (C² atoms) of LDH (to be viewed with stereo glasses). *b*, Schematic diagram of the main chain of LDH in the same orientation as Fig. 1*a*, showing the relative positions of the α-helices (cylinders) and β-strands (ribbons). *c*, A highly schematic diagram of LDH showing the relative positions of α-helices (○) and β-strands (Δ and ▽ according to whether viewed from the N- or the C-terminus of the strand). *d*, A section of polypeptide chain showing all the atoms and the dihedral angles φ and ψ. *e*, Simplification of (*d*) used by Levitt and Warshel^{52,55} to predict structure.

structure: α-helix, β-strand, coil, and sometimes β-turn. The observed distribution of amino acids amongst these classes is then used to derive parameters for the probability that a particular amino acid type will adopt a given class of secondary structure. The methods vary both in how the parameters are derived and how they are then used to predict structure. Some schemes sum the effects of individual residues^{18–20} while others also incorporate pair and/or triplet information^{21–24}. The method of Chou and Fasman¹⁹ has attracted most attention as it is simple to understand, can be applied without a computer, and has been relatively successful.

Second, there are a few methods^{25–27} which do not incorporate statistical data but are based on stereochemical criteria. Lim²⁷ has considered both the hydrophobicity and size of side chains to propose favourable patterns of residues that will form α-helices and β-strands. This apparently complex method, once understood, can be applied easily without a computer. It is appealing because it emphasises the importance of the positions of hydrophobic and hydrophilic residues and also incorporates, to some extent, long-range interactions.

Schulz²⁸ and Matthews²⁹ combined the results of several predictions to obtain joint prediction histograms for adenyl kinase and bacteriophage T4 lysozyme, respectively. The joint predictions were shown to be comparable with the best single prediction. This combined approach has been computerised by Argos *et al.*³⁰ who then applied it to 20 independent protein structures. An advantage of this completely computerised method is that it is impartial, whereas some of the individual schemes require human intervention to make the final assignments. The following generalisations about secondary structure prediction can be made.

No individual method is clearly superior. The success of a prediction for helices can be measured by a correlation coefficient C_α (ref. 29), where $C_\alpha = 1$, indicates a perfect prediction, while $C_\alpha = 0$, indicates a random prediction. C_β and C_T are similarly defined for predictions of β-strands and β-turns, respectively. The success of a given scheme varies considerably between proteins. Better predictions are generally obtained for small thermostable monomeric proteins than for the larger molecular weight structures. Argos *et al.*³⁰ find a range of values of $C_\alpha = 0.2$ to 0.86,

$C_\beta = 0.03$ to 0.73 and $C_T = 0.10$ to 0.84 . Thus the predictions were better than random for all structures. Although most of the α -helices and more than half of the β -strands and β -turns are located roughly, there are often errors in determining their termini. Presumably α -helices are predicted more accurately as local interactions are particularly important in their formation. Often the amino-terminal half of protein is predicted better than the carboxyl-terminal half, suggesting an amino-terminal nucleating core, in which short-range interactions dominate.

The success of predictive schemes has not greatly improved since 1974 although more protein structures are now available. This suggests that failure to achieve 100% accuracy is not the result of limited data, but that the formation of secondary structure is also determined by long-range interactions, which are not adequately considered.

Analysis of tertiary structure

The globular tertiary structure of a protein is stabilised by long-range interactions, which occur between non-local sections of sequence, for example the packing between two helices. With the increase in the number of protein structures known, many common structural features have been recognised, which were not previously predicted, and it has become apparent that proteins follow certain 'folding rules', which help determine tertiary structure. The simplification of the complex tertiary structure by the use of schematic diagrams (Fig. 1b, c) has helped in the understanding and comparison of protein structures. The results of analyses of tertiary structure, which are important for structure prediction, will be described.

Inspection of detailed interatomic interactions shows that two features are important determinants of protein structure. All proteins are closely packed, with packing densities comparable to those of small organic crystals³¹. This requirement for close-packing restricts the observed packing angles of α -helices and β -sheets to a few categories³². Second, hydrophobic groups tend

to be buried inside the protein forming a non-polar core, while hydrophilic side chains are nearly always exposed³³. Nearly all the buried polar groups, such as the main-chain $-\text{NH}$ and $-\text{CO}$ groups form hydrogen bonds³⁴. Consequently chain reversals almost always occur near the surface of the molecule³⁵ while large parts of the α -helices and β -sheets are buried. Any realistic prediction must aim to satisfy both these requirements.

Further restrictions on possible conformations occur because of the chirality of L-amino acids. In particular: (1) α -helices are right-handed. (2) β -sheets have a right-handed twist of the peptide units along the β -strand and, consequently, a left-handed rotation between adjacent strands³⁶ (Fig. 2a). (3) The connection between two parallel strands in the same sheet will almost certainly be right-handed (Fig. 2b)³⁷⁻³⁹. (4) Cylindrical sheets (that is β -barrels) are right-handed (Fig. 2c)⁴⁰. The first requirement for right-handed α -helices can be incorporated into a conventional energy minimisation (see later), but the remaining observations refer more specifically to tertiary structure and suggest that a model-building approach to protein prediction could be useful.

One of the main difficulties in predicting tertiary structure is to determine which segments of chain will lie close together. It has been observed that elements of secondary structure which are sequential along the polypeptide chain tend to lie proximate in the three-dimensional structure⁴¹. Furthermore analyses of β -sheets have suggested several preferences which help determine strand order^{42,43}. For example, the last sequential strand in the sheet preferentially occupies an edge position. Similarly the most hydrophobic strands generally occupy central positions in the sheet, with the more hydrophilic strands at the edge⁴⁴. These preferences should also be incorporated into prediction schemes (see later).

Several features of the overall fold have been recognised. Certain tertiary structures of more than an individual α -helix or β -sheet are often observed and appear to act as 'building blocks' or 'super-secondary structures'⁴⁵. Large proteins are often divided into a few distinct structural regions, called domains. These

Fig. 2 Results of analysis of protein structure. *a*, A twisted β -sheet: schematic diagram of three β -strands viewed normal to their direction to show the left-handed rotation between them that is always observed³⁶. *b*, Two parallel β -strands, viewed normal to their direction, and a connecting region. The right-handed structure is nearly always observed whereas the left-handed structure occurs rarely³⁷⁻³⁹. This may be because the left-handed rotation between β -strands gives a direct connection for the right-handed structure³⁷. *c*, The handedness of the β -barrel. In all observed barrels the strands are inclined to the axis so as to form a right-handed structure⁴⁰, that is if the strands were extended they would tend to form a right-handed helix about the barrel axis. This handedness is a consequence of the twist of the β -sheet. The alternative left-handed structure has not been observed. *d*, Classes of protein structure⁴¹. MBN-myoglobin, an α -protein; PRE-prealbumin, a β -protein; LYS-hen egg white lysozyme, an $\alpha + \beta$ protein; TIM-triose phosphate isomerase, an α/β protein.

domains contain 40–250 residues. Finally most protein structures fall into five rather distinct classes⁴¹ which are defined according to secondary structure content (Fig. 2d): α -proteins have only α -helix; β proteins have mainly β -sheet; $\alpha + \beta$ proteins have α -helix and β -strand secondary structural segments that do not mix but tend to segregate along the polypeptide chain; α/β have mixed or approximately alternating segments of α -helix and β -strand; and 'coil' proteins contain almost no regular secondary structure. We have noted that intracellular proteins usually fall into the α or α/β classes, and almost never have disulphide bridges. In contrast, extracellular proteins are usually all β or $\alpha + \beta$ type.

Once a protein sequence is known and a secondary structure prediction has been performed, these observations will help to predict the correct tertiary structure. Although some of these results have already been used, most of this work has yet to make its impact on prediction.

Tertiary structure prediction from evolutionary relationships

Families of homologous proteins, for example the cytochromes c, have almost identical main-chain structures but only similar sequences, suggesting that structure evolves more slowly than sequence⁴⁶. Observed structures can therefore be used to predict unknown structures of proteins with related sequences. For example, the fold of α -lactalbumin has been correctly predicted on the basis of its sequence similarity with hen egg white lysozyme⁴⁷. Similarly, a structure for troponin C was predicted from the crystal structure of myogen in conjunction with symmetry requirements⁴⁸. Recently, sequences that show very little similarity have been observed to adopt similar fold, for example in the case of the dehydrogenases⁴⁹. This has proved useful for prediction, although it is debatable whether these similarities result from convergent or divergent evolution. For example, parts of aldolase⁵⁰ and glutamate dehydrogenase⁵¹ have been predicted to fold in a similar six-stranded structure to lactate dehydrogenase. This is based on secondary structure prediction, sequence resemblances with the dehydrogenases and, for aldolase, recognition of the fold by affinity chromatography⁵⁰.

One can envisage that grouping proteins into families may be used widely to predict structure. Furthermore many proteins have evolved by gene replication or gene fusion, and the structural consequences of this may also be useful for prediction. However, this type of approach is necessarily restricted to related proteins.

Prediction of tertiary structure

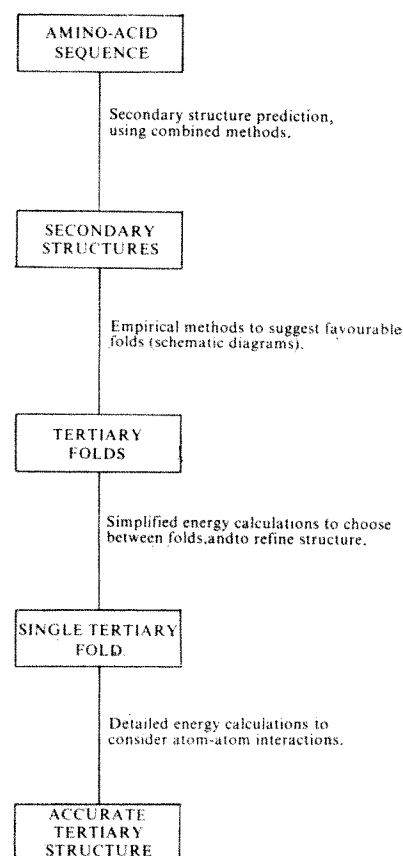

Predictions of the tertiary structure of a protein by more general methods have been made only very recently. At this early stage the predictions have been limited to small proteins whose structures are already known. There are several completely different approaches.

The semi-empirical energy calculations described previously have been modified to treat proteins by a simplification of energy functions and protein structure representation (Fig. 1e), followed by energy minimisation^{52–55}. These methods are based on the assumptions that: (1) the fine details of protein structure can be time-averaged and are not vital for the formation of the correct fold of the polypeptide chain; (2) only variables that have the greatest effect on folding need be considered; (3) the major determinants of the protein fold are the requirement for close-packing (van der Waals interactions), good hydrophobic burial and hydrophilic exposure (solvent interactions) and sometimes the ϕ - ψ preference of certain amino acid types. Probably the choice of these determinants was influenced by the analyses of known structures. These simplifications were introduced by Levitt and Warshel⁵². They represented each amino acid residue by two centres, the C α atom and a single sphere positioned at the centroid of the side chain (Fig. 1e). The interactions were between these centres. Only one degree of freedom—the torsion angle α about a line joining consecutive C α atoms—was allowed per residue⁵⁵. Minimisation of the energy function was followed by 'thermalisation' to escape from local minima. The method was

applied to pancreatic trypsin inhibitor (58 residues with one α -helix of ten residues) and myogen (108 residues with six α -helices). Generally residues that formed α -helices were preset to their correct conformation and held rigid during the calculation. A similar algorithm has been developed by Kuntz *et al.*⁵³ who minimised an error function which incorporated hydrophobic/hydrophilic interactions, steric repulsion and correct disulphide and iron-sulphur bonding. The structure of trypsin inhibitor and rubredoxin (53 residues) were predicted. Tanaka and Scheraga⁵⁴ have outlined a third method which shares some features with the two approaches described above. Each side chain is represented by a single sphere and the interactions between pairs of residues is estimated from an analysis of close contacts in 25 proteins of known structure. The secondary structure for each residue was predicted. Low energy conformations were found by a random 'Monte-Carlo' search, rather than by minimisation. The method was applied to trypsin inhibitor.

The success of these methods can be measured as the r.m.s. deviation of the predicted structure coordinates from the observed structure. Levitt and Warshel obtained r.m.s. errors of 5–7 Å for trypsin inhibitor. Conformations that deviated more from the native structure always had higher energies, which gives an independent criterion for choosing the best conformation. They had less success with myogen, obtaining only three structures with r.m.s. values less than 8.5 Å, even assuming rigid helices. Similarly Kuntz *et al.* obtained a number of structures for each protein with r.m.s. errors of 4 to 6.5 Å for trypsin inhibitor and rubredoxin (note: the disulphide and sulphur-iron bonding was forced to be correct). In both methods some, though by no means all, of the minimised structures had the correct fold, with bends and loops approximately located and the correct long-range interactions. Myogen was the most noticeable exception, since even the structures with lowest r.m.s. errors showed an incorrect fold. Tanaka and Scheraga do not give r.m.s. values but claim to have obtained some agreement with the native structure.

Fig. 3 A possible approach to predicting tertiary structure from amino acid sequence using a combination of methods.

Several serious points arise from consideration of these results. These methods have not yet been sufficiently tested for it to be clear whether they will be generally useful and whether the assumptions made are valid. Their application to larger proteins is difficult to envisage since the computing time will increase rapidly and larger structures are more complex. Levitt (personal communication) has suggested that compact structures of trypsin inhibitor, generated by a self-avoiding random walk, are almost as close to the native structure as some of the better structures obtained from energy minimisation. Thus it is questionable whether the simple structural representation and energy minimisation techniques are adequate. Finally, it is difficult to see how many of the empirical observations on tertiary structure can be incorporated into this kind of approach.

Overall, the results of these simplified energy calculations were very encouraging. Starting from a fully extended conformation, proteins have been folded into compact structures which show many similarities to the native states. It is to be hoped that these methods will be more fully explored and refined to give improved predictions.

A different type of approach to predict the structure of α -helical proteins has been described by Ptitsyn and Rashin⁵⁶, used by Lim and Efimov⁵⁷, and modified for application to β -sheet proteins by Zav'yalov⁵⁸. There are two basic assumptions. First, folding proceeds by a stepwise process in which fluctuating regions of secondary structure are formed and then condense into a single compact globule. Second, the condensation process is determined by three considerations: (1) Regions of secondary structure, which are adjacent along the polypeptide chain, will tend to lie proximate in the tertiary structure. (2) At each stage of the folding pathway only the most favourable structures are maintained and all other structures rejected. (3) Packing will occur so as to maximise the reduction of hydrophobic free energy, by the exposure of hydrophilic groups and burial of hydrophobic side chains.

Thus Ptitsyn and Rashin⁵⁶ took the residues forming α -helices in myoglobin from the native structure and modelled these α -helices by cylinders. A manual search was performed for the packing between adjacent helices which gave optimal reduction in hydrophobic free energy. They were able to predict the correct native fold. Similarly Lim and Efimov have folded tobacco mosaic virus protein. Zav'yalov⁵⁸, assuming the hairpin bends in the immunoglobulin domain, predicted the structure of the β -sheet sandwich. The success of this approach indicates the importance of hydrophobic free energy and close-packing of secondary structures in determining tertiary structure. The major problem is that the method is non-automated and therefore difficult to apply impartially. However a computerised method based on this approach, which incorporates the packing rules for secondary structures³² and includes some calculation of hydrophobic free energy could prove successful.

Most recently a different approach has been considered in which, rather than energy calculations, folding rules obtained from the analyses of structures are used for prediction. We have used the results from a quantitative analysis of β -sheets to derive a folding parameter which represents whether a particular arrangement of strands in a sheet is favourable⁵⁹. This approach involves a further level of simplification: the calculations only consider the relative positions and type of connections of the strands (as in Fig. 1c) and do not evaluate residue-residue interactions. To explore this approach, the location of the secondary structure along the chain and the assignment of strands to a particular sheet were taken from the observed structure. For 25 out of the 52 sheets examined, the actual arrangement is the sheet, or one of the sheets, with the most favourable folding parameter and therefore could have been readily predicted. This surprisingly good result suggests that strand order is somewhat determined by a few elementary folding rules.

Nagano (personal communication) has suggested another empirical approach to predicting probable packing arrangements of α -helices and β -strands in α/β type proteins. First, regions of the sequence that are likely to be predicted as α or β secondary

structures are located. Then hypothetical rules are used to suggest packing arrangements whose stability is evaluated by an empirical penalty function. Thus he builds up a schematic diagram of the protein structure (like that in Fig. 1c). The generality of this method has still to be determined. However it is a novel approach, which has the advantage of starting from the sequence and translating right through to the tertiary structure.

These empirical methods, by their simplicity, can be applied to larger proteins whose size puts them beyond the scope of conventional methods. The approaches consider the structural features which result from both the stability of the final structure and the kinetics of protein folding, without any assumptions about the folding process. They should be useful to predict probable folds which then can be examined by energy calculations.

Outlook

Although the individual methods of structure prediction will doubtless be extended and improved, it is likely that the answer to the folding problem lies in a combination of the available approaches. One combination is outlined in Fig. 3. This shows how, starting with the sequence, one can progress through the secondary structure analysis and the prediction of tertiary fold to simplified and then detailed energy calculations. Feedback at each stage is important, so that, for example, the final choice of secondary structure must be influenced by consideration of which tertiary folds are favourable. For an individual protein, biochemical data (for example, which residues are involved in the active site) can be incorporated, either to suggest which of the tertiary folds should be chosen, or to test the feasibility of the final predicted structure. Perhaps the major improvements to prediction will come from further renaturation and X-ray studies, which will provide more information on folding pathways and the final structure. Clearly the last few years have witnessed the development of many novel approaches to the prediction of tertiary structure. Hopefully these preliminary investigations will provide the first steps towards the solution of the folding problem.

We thank: Professor D. C. Phillips for encouragement and advice; Dr I. A. Wilson for help in preparation of the stereo diagram; Dr Olga Kennard for supplying coordinates of lactate dehydrogenase from the Cambridge Data Bank; Professor M. G. Rossmann and Academic Press, New York, for allowing us to reproduce Fig. 7 from reference 49; and the Medical Research Council for financial support.

SU(2) × U(1): A gauge theory of weak interactions?

David Bailin & Norman Dombey

School of Mathematical and Physical Sciences, University of Sussex, Falmer, Brighton, Sussex, UK

We construct a gauge theory of weak interactions which fits all neutral current data, including the atomic physics experiments. It is shown that it is possible to include this theory in a unified theory of weak and electromagnetic interactions; the desirability of doing so is discussed.

IN 1967 Weinberg¹ wrote down a renormalisable unified gauge theory of weak and electromagnetic interactions based on the spontaneously broken gauge group SU(2) × U(1). This model involves the existence of a weak neutral current coupled to neutrinos, and weak neutral currents were discovered experimentally² in neutrino scattering in 1973. So it has been a great temptation for physicists, especially theorists, to claim that the discovery of neutral currents is a confirmation of the Weinberg model and in particular shows the unification of weak and electromagnetic interactions.

This view although widespread has been forcefully criticised, especially by Sakurai³. He argues that neutral current phenomena are interesting in their own right, and that it is the job of physicists to discover through experiment the relevant couplings not to assume the results in advance. Nevertheless the Weinberg model has been very successful and all neutrino data up to now are consistent with a single value of $\sin^2\theta_w$. The model is obviously useful as it not only provides a means of analysing experiments but it also suggests new experiments. In Bjorken's words⁴ it is a "working hypothesis". In particular in its simplest form it gives definite predictions of parity violation in heavy atoms which were not observed in recent experiments at Oxford and Washington⁵.

The purpose of this article is to point out another possibility. The starting point is a remark made some years ago⁶: the requirement that the theory of weak interactions is renormalisable has nothing *a priori* to do with unification of weak and electromagnetic interactions. After all it is (or at least was) customary to treat strong, electromagnetic and weak interactions independently of each other.

We shall treat this remark perhaps more seriously than it deserves in order to construct a new working hypothesis. We shall write down a SU(2) × U(1) gauge theory of weak interactions which as far as neutrino interactions are concerned allows an almost identical analysis of the present data. This theory gives parity violation in heavy atoms but the magnitude of the effect predicted is now in agreement with experiment. The theory is renormalisable in the absence of electromagnetic and strong interactions.

We shall construct our weak SU(2) × U(1) model first and discuss its difficulties afterwards. We start with the leptonic

sector. Following Weinberg we take a doublet $L = (\nu, e)_L$ of left-handed leptons and a right-handed lepton singlet $R = e_R$ with a Lagrangian

$$\mathcal{L} = i\bar{L}\gamma^\mu(\partial_\mu + \frac{1}{2}ig\tau\cdot\mathbf{W}_\mu - \frac{1}{2}ig'B_\mu)L + i\bar{R}\gamma_\mu(\partial_\mu - irB_\mu)R + \mathcal{P} \quad (1)$$

where \mathcal{P} involves the meson-meson couplings required by gauge invariance.

Take

$$\begin{aligned} Z_\mu &= W_\mu^3 \cos\theta_w - B_\mu \sin\theta_w \\ X_\mu &= W_\mu^3 \sin\theta_w + B_\mu \cos\theta_w. \end{aligned} \quad (2)$$

In the unified theory X^0 is the photon and the constraints are (1) no $\bar{\nu}\nu X^0$ coupling and (2) the $\bar{e}eX^0$ coupling is pure vector. These conditions give $g' = g \tan\theta_w$ and $r = g'$. This leads to a Lagrangian

$$\begin{aligned} \mathcal{L} &= \mathcal{L}_0 - \frac{g}{2\sqrt{2}}[\bar{\nu}\gamma^\alpha(1-\gamma_5)eW_\alpha^+ + h.c.] \\ &- \frac{g'}{4\sin\theta_w}Z^\alpha[\bar{\nu}\gamma_\alpha(1-\gamma_5)\nu - (1-4\sin^2\theta_w)\bar{e}\gamma_\alpha e + \bar{e}\gamma_\alpha\gamma_5 e] \\ &+ g\sin\theta_w X^\alpha \bar{e}\gamma_\alpha e + \mathcal{P}. \end{aligned} \quad (3)$$

In weak SU(2) × U(1) X^0 is not the photon but a second neutral vector meson. The requirement that there should be the same relation between neutrino scattering by charged currents and neutral currents in this model as in the unified theory implies again that there is no $\bar{\nu}\nu X^0$ coupling. So again $g' = g \tan\theta_w$. In order to obtain a distinct alternative theory we require now that the $\bar{e}eX^0$ coupling is pure axial. This gives $r = -g'$. With these choices the Lagrangian becomes

$$\begin{aligned} \mathcal{L} &= \mathcal{L}_0 - \frac{g}{2\sqrt{2}}[\bar{\nu}\gamma^\alpha(1-\gamma_5)eW_\alpha^+ + h.c.] \\ &- \frac{g'}{4\sin\theta_w}Z^\alpha[\bar{\nu}\gamma_\alpha(1-\gamma_5)\nu + (1-4\sin^2\theta_w)\bar{e}\gamma_\alpha\gamma_5 e - \bar{e}\gamma_\alpha e] \\ &- g\sin\theta_w X^\alpha \bar{e}\gamma_\alpha\gamma_5 e + \mathcal{P}. \end{aligned} \quad (4)$$

Comparing the Lagrangians (3) and (4) we see that there is no difference in neutrino couplings but that in the $\bar{e}eZ^0$ couplings the vector and axial currents are interchanged.

The GIM⁷ mechanism can now be used as in the unified theory to construct the weak hadronic interaction. We will not display

the result; all we need is that whereas in unified $SU(2) \times U(1)$ the $\Delta S = \Delta C = 0$ neutral weak hadronic current is

$$J_\mu = A_\mu^3 + (1 - 2\sin^2\theta_w)V_\mu^3 - 2\sin^2\theta_w A_\mu^S, \quad (5)$$

in weak $SU(2) \times U(1)$ the current coupling to Z^0 is

$$J_\mu = V_\mu^3 + (1 - 2\sin^2\theta_w)A_\mu^3 - 2\sin^2\theta_w A_\mu^S, \quad (6)$$

where V_μ and A_μ are the vector and axial vector currents, and 3 and S refer to the isovector and isoscalar components. There is also a purely axial current which couples to X which will not contribute to neutrino scattering.

Before turning to the neutral current data, we must define the strength of neutral current neutrino processes compared with charged current processes in the effective current theory. The Fermi constant G for charged currents is given in terms of the W^\pm mass m_w by

$$\frac{G}{\sqrt{2}} = \frac{g^2}{8m_w^2}. \quad (7)$$

Similarly, if the Fermi constant for neutral currents is G' , then from equation (4)

$$\frac{G'}{\sqrt{2}} = \frac{g'^2}{16m_z^2\sin^2\theta_w} = \frac{g^2}{16m_w^2\kappa^2} \quad (8)$$

where $\kappa = m_z \cos\theta_w / m_w$. In the Weinberg model $\kappa = 1$. (Note that Salam and Ward⁸, following Glashow⁹, wrote down an $SU(2) \times U(1)$ unified gauge theory in 1964. As it was not a spontaneously broken gauge theory, however, it was not renormalisable and there were no predictions of the 'vector mesons' masses. Thus the structure of their weak neutral current is that given by Weinberg, but the relative strength of the neutral current compared with the charged current in neutrino interactions is not specified. Only with a detailed symmetry breaking mechanism can κ be predicted and in our opinion this is the distinguishing feature of Weinberg's model.)

Experimentally $\kappa^2 = 0.97 \pm 0.13$ (ref. 10). In weak $SU(2) \times U(1)$ we will show shortly that $\kappa < 1$, but for the moment we assume that the value predicted is in agreement with experiment. We can now analyse the neutral current data.

Inclusive neutrino reactions

The well-known vector-axial ambiguity¹¹ implies that the results in our model are identical with those of the unified $SU(2) \times U(1)$ model. Thus we can use the Weinberg angle measured in these experiments. The most recent values¹² are $\sin^2\theta_w = 0.31 \pm 0.03$ or $\sin^2\theta_w = 0.26 \pm 0.02$, depending on whether the CDHS (CERN-Dortmund-Heidelberg-Saclay) data is included. We shall be conservative and take $0.24 \leq \sin^2\theta_w \leq 0.34$.

Neutrino-lepton scattering

Again, there is no effect when vector and axial currents are interchanged. So the results of unified $SU(2) \times U(1)$ model are true in weak $SU(2) \times U(1)$.

Elastic νp scattering

The cross section in exclusive channels is not invariant under the interchange of vector and axial vector currents. For example, in the forward direction we have in the Weinberg model from equation (5)

$$R = \lim_{q^2 \rightarrow 0} \left[\frac{d\sigma}{dq^2}(\nu p \rightarrow \nu p) / \frac{d\sigma}{dq^2}(\nu n \rightarrow \mu^- p) \right] \\ = \frac{1}{4}[(1 - 4\sin^2\theta_w)^2 + (g_A^3)^2] / [1 + (g_A^3)^2], \quad (9)$$

where $g_A^3 = -1.25$ is the isovector axial renormalisation factor. In weak $SU(2) \times U(1)$ we have from equation (6)

$$R = \frac{1}{4\kappa^2} [1 + \{(1 - 2\sin^2\theta_w)g_A^3 - 2\sin^2\theta_w g_A^S\}^2 / [1 + (g_A^3)^2]]. \quad (10)$$

The isoscalar axial renormalisation factor g_A^S is not experimentally known, but a reasonably reliable quark model estimate¹³ is $g_A^S = \frac{2}{3}g_A^3$. Putting in the values for the parameters we obtain in the Weinberg model $0.15 < R < 0.17$, whereas in weak $SU(2) \times U(1)$ $R = 0.10/\kappa^2$ and the dependence on g_A^S is not very sensitive.

The data are not yet good enough to determine more than total cross sections integrated over all q^2 . For this assumptions must be made about axial form factor behaviour which are not well known, and it is safe to say that any conclusion drawn on the basis of the Weinberg model can be matched in weak $SU(2) \times U(1)$.

Single pion production

This process is very difficult to analyse as most of the data come from heavy liquid bubble chambers where nuclear charge exchange effects are important. There is data from Argonne¹⁴ in hydrogen and deuterium but the errors are still very large. So again it is unlikely that any prediction could be made on the basis of unified $SU(2) \times U(1)$ which could not be reproduced in weak $SU(2) \times U(1)$.

Comparing equations (5) and (6) we see that A_μ^3 is suppressed in weak $SU(2) \times U(1)$ compared with in the Weinberg model, whereas V_μ^3 is enhanced. As A_μ^3 gives the dominant transition in the Δ -resonance region, a calculation of the cross section for a given value of $\sin^2\theta_w$ would give a lower value in weak $SU(2) \times U(1)$ than in unified $SU(2) \times U(1)$. The theoretical analysis¹⁵ of weak pion production in unified $SU(2) \times U(1)$ shows that cross sections decrease as $\sin^2\theta_w$ increases. Hence if weak $SU(2) \times U(1)$ is right an analysis of this process in unified $SU(2) \times U(1)$ would give a relatively large value of $\sin^2\theta_w$.

Parity violation in atoms

Z^0 exchange between an atomic electron and the nucleus will not conserve parity. This effect arises both from a vector interaction at the electron together with an axial interaction at the nucleus, and from an axial interaction at the electron together with a vector interaction at the nucleus. Taking the nucleus as static the latter term will dominate in heavy nuclei as it gives a coherent contribution over the whole nucleus. In the Weinberg model the coefficient of the axial coupling is taken as unity from equation (3) whereas the nuclear vector contribution from equation (5) gives an overall effect

$$Q_w = (1 - 4\sin^2\theta_w)Z - N. \quad (11)$$

Numerically in bismuth $123 < -Q_w < 156$. From the experiment⁵, the observed value of Q_w in bismuth is no larger than one-tenth of the maximum value predicted by the Weinberg model together with the standard atomic theory. The standard atomic theory should be good to at least a factor two¹⁶, so it is fair to say that $|Q_w| < 32$ for bismuth.

In weak $SU(2) \times U(1)$ we have a factor $1 - 4\sin^2\theta_w$ for the axial coupling from equation (4), and the nuclear vector coupling is pure isovector from equation (6). The exchange of X^0 conserves parity. So now

$$Q_w = (1 - 4\sin^2\theta_w)(Z - N)/\kappa^2 \quad (12)$$

or in bismuth $-2 < Q_w\kappa^2 < 15$, which is not in disagreement with the experiments.

If $\sin^2\theta_w = \frac{1}{4}$ then $Q_w = 0$, as the $\bar{e}eX^0$ coupling is now pure vector. This would rule out any coherent effect although there would still be parity violation from the axial coupling of the nucleus. This would be seen most clearly in experiments on

hydrogen or deuterium or in the experiment to measure a macroscopic electric dipole moment in superfluid Helium 3 suggested by Leggett¹⁷. It is also worth noting that for $\sin^2\theta_w = \frac{1}{4}$ in weak $SU(2) \times U(1)$ there is no parity violation in purely leptonic neutral current interactions. So there is no forward-backward asymmetry in $e^+e^- \rightarrow \mu^+\mu^-$ and $\sigma(\nu_\mu e^-) = \sigma(\bar{\nu}_\mu e^-)$.

We now turn to the mass relations of the gauge particles in weak $SU(2) \times U(1)$. We require spontaneous breaking with respect to $SU(2)$ through a single isospinor complex scalar field as in the Weinberg theory, but now we also spontaneously break the $U(1)$ through an isoscalar complex scalar field, as the current coupled to the X^0 is no longer conserved. Thus two Higgs scalars result and the particles W^\pm , X^0 , Z^0 acquire mass. The mass relations follow from the mixing equations

$$\begin{aligned} m_x^2 &= m_w^2 \sin^2\theta_w + m_B^2 \cos^2\theta_w + 2m_{wB}^2 \sin\theta_w \cos\theta_w \\ m_z^2 &= m_w^2 \cos^2\theta_w + m_B^2 \sin^2\theta_w - 2m_{wB}^2 \sin\theta_w \cos\theta_w \\ 0 &= m_{wB}^2 (\cos^2\theta_w - \sin^2\theta_w) + (m_w^2 - m_B^2) \sin\theta_w \cos\theta_w \end{aligned} \quad (13)$$

where m_{wB}^2 is the off-diagonal element of the mass matrix. So

$$m_w^2 = m_z^2 \cos^2\theta_w + m_x^2 \sin^2\theta_w. \quad (14)$$

For $m_x = 0$ this reduces to $m_w = m_z \cos\theta_w$ and $\kappa = 1$, as in the Weinberg model. Now, however, we are constrained by the experimental value of κ . Since $\kappa \sim 1$, m_x cannot be too large. Nevertheless, since the data allow $\kappa^2 > 0.84$, the previously given bounds on $\sin^2\theta_w$ enable us to deduce from equation (14) that $m_x/m_w < 0.7-0.8$.

Note that there is no difficulty in giving mass to X^0 , so it cannot be claimed that a photon is a necessary concomitant of the theory. If the gauge group were simple, as in the Georgi-Glashow model¹⁸, and if the symmetry breaking were through the regular representation¹⁹, then it would be natural to have a zero mass vector meson in the theory: theories of this type are discussed elsewhere²⁰. In weak $SU(2) \times U(1)$ the value of m_w is not constrained. In unified $SU(2) \times U(1)$ $g \sin\theta_w = e$ and using equation (7) this fixes the mass scale of the theory so that $m_w > 37$ GeV. In weak $SU(2) \times U(1)$ g is just the weak coupling constant and is arbitrary. Indeed this model is flexible: if no vector mesons are found then the limit $g \rightarrow \infty$, $m_w \rightarrow \infty$ can be taken and the old four-fermion theory reappears.

It is now time to mention the difficulty of a gauge theory of weak interactions which leaves out electromagnetism. The process $e^+e^- \rightarrow W^+W^-$ through one photon exchange displays all the old problems associated with charged spin on particles. In general the electromagnetic corrections to the theory are not renormalisable.

Of course the obvious way out of this difficulty is to reunify the theory after all by including the photon as a gauge particle and enlarging the group. The minimal extension of weak $SU(2) \times U(1)$ is $SU(2) \times U(1) \times U(1)$, where the new $U(1)$ is characterised by another isoscalar vector meson C_μ and the photon field

$$a_\mu = W_\mu^3 \sin\psi + C_\mu \cos\psi. \quad (15)$$

Then, as the resultant theory is unified, $e = g \sin\psi$, and immediately we obtain the unified mass scale $m_w = 37/|\sin\psi|$ GeV. Provided $\sin\psi$ is reasonably small all the results of weak $SU(2) \times U(1)$ will still hold, up to an error of order $|\sin\psi|$. There is now no connection between $\sin\theta_w$ determined from neutrino scattering and m_w . Equation (14) still holds approximately and so although W^\pm must now have a large mass X^0 can still be light²¹.

The historic reasons^{8,9} for a non-Abelian gauge theory of weak interactions are that these involve charged currents which are conserved—the natural way of ensuring this is to construct a gauge theory. Alternative possibilities to a unified theory of weak and electromagnetic interactions are suggested by analogy with strong interaction theory where there were also good reasons for writing a non-Abelian gauge theory in order to explain isotopic spin conservation. Sakurai²² introduced the ρ meson as a gauge particle for this purpose. Gell-Mann²³ constructed the $SU(3)$

symmetry among interactions by generalising these ideas. Yet these theories involved charged vector mesons ρ^\pm and therefore were open to the same criticism as here: these theories are non-renormalisable in the presence of electromagnetism.

These criticisms are no longer relevant. The modern picture of ρ^\pm is a composite of two spin- $\frac{1}{2}$ particles, a quark-antiquark pair. The ultra-high energy behaviour of $e^+e^- \rightarrow W^+W^-$ similarly depends on the internal electromagnetic structure of W^\pm . Form factors arising from a composite nature (a pair of quarks, heavy leptons, leptoquarks?) or a hidden strong interaction of W^\pm could save the day. So could a reinterpretation of quantum electrodynamics for high spin particles along the lines suggested by Lee and Yang².

All gauge theories require the existence of intermediate vector mesons. In a unified gauge theory the mass scale is fixed: $m_w \sim e/G^{1/2} \approx 38$ GeV. In a weak gauge theory this is not necessarily so, and, if weak interactions were really weak at all energies, we would expect relatively light W^\pm , for example if $g^2/4\pi = 10^{-3}$, then $m_w = 14$ GeV. Experimentally the lower limit on m_w is 1 GeV (D. H. Perkins, personal communication).

In weak $SU(2) \times U(1)$ a neutral vector meson X^0 exists which must be lighter than W^\pm . It has not yet been observed in e^+e^- colliding beam experiments at SPEAR, so $m_x > 7.6$ GeV (ref. 25). It could be identified by its (relatively) narrow width

$$\Gamma = (2+R) \frac{G^2/2}{3\pi} m_x^2 \sin^2\theta_w \quad (16)$$

where in this model R is the cross section ratio $\sigma(e^+e^- \rightarrow \text{hadrons})/\sigma(e^+e^- \rightarrow \mu^+\mu^-)$ at centre-of mass energy m_x . So if $m_x = 10$ GeV and $m_w = 90$ GeV, then $\Gamma \sim 250$ MeV.

We should emphasise that even if the theory is unified, so that $SU(2) \times U(1) \times U(1)$ or a larger group such as $SU(2) \times SU(2) \times U(1)$ (refs 26, 27) or $SU(3) \times U(1)$ (ref. 28) is applicable, it may still be useful to consider weak $SU(2) \times U(1)$ as an approximate symmetry for weak interactions. Indeed the Weinberg model is perhaps too constrained a theory. In weak $SU(2) \times U(1)$ $\sin\theta_w$ fixes the form of the neutral currents but it does not fix the strength relative to the charged current; for that κ is needed, where $\kappa \neq 1$. Again, in the Weinberg model the neutral vector meson must be heavier than W^\pm , while in weak $SU(2) \times U(1)$ the X^0 can be arbitrarily light. Only if and when the vector mesons are found can definite statements be made about the underlying theory. It follows that experimentalists should continue to look for W^\pm and neutral weak vector mesons, and not assume that the success of the Weinberg model implies that they can only be found with a new generation of accelerators.

Finally we point out that there is one good (if not compelling) reason for the unification of weak and electromagnetic interactions which results from experiment. This comes about by inverting the argument of Wilkinson²⁹ on the radiative corrections to vector current universality. If the observed muon decay rate is compared with nuclear ft-values, it is found that

$$\Delta \equiv 2\{g_{\beta\nu}^R/g_\mu^R \cos\theta_c - 1\} = 2.19 \pm 0.27\% \quad (17)$$

where $g_{\beta\nu}^R$ and g_μ^R are the effective β decay and muon decay coupling constants (after removing the well-understood 'outer' radiative corrections) and θ_c is the Cabibbo angle. Theoretically the purely electromagnetic contribution to Δ , arising from the 'inner' (short distance) radiative corrections gives a divergent contribution³⁰

$$\Delta = \frac{3\alpha}{2\pi} (1 + 2\bar{Q})(\ln(\Lambda/m_N)) \quad (18)$$

where Λ is a cut-off and \bar{Q} is the average charge of the quark constituents of the nucleon. Assuming $\bar{Q} = \frac{1}{6}$, as is appropriate for both the conventional Gell-Mann Zweig quarks used throughout this analysis and integrally charged Han Nambu quarks³¹, we obtain from equations (16) and (17) that $\Lambda \approx 90$ GeV.

In a unified theory of weak and electromagnetic interactions the average mass of the gauge vector mesons would provide an

effective cut-off³²⁻³⁴. So we conclude that this result implies that the value of m_w is about 90 GeV (ref. 35), which is consistent with the mass scale expected in a unified theory.

We thank Roger Blin-Stoyle, Alex Love, Don Perkins and Patrick Sandars for discussions.

Granite-greenstone terrain Rhodesian Archaean craton

J. F. Wilson

Department of Geology, University of Rhodesia, Salisbury, Rhodesia

M. J. Bickle, C. J. Hawkesworth

Department of Earth Sciences, University of Leeds, Leeds, UK

A. Martin

Granite-greenstone terrains of possibly three different ages exist in the Rhodesian Archaean craton. Their respective greenstone belts can be tentatively delineated across the central cratonic area. The main stratigraphic units of the youngest (~ 2,700 Myr) and most widespread development can be correlated across greenstone belts in this area. Major events in the craton are summarised and briefly discussed in the light of the new correlations and recent age determinations.

A REVIEW¹ of available field and geochronological data allows the recognition and partial delineation of granite-greenstone terrains of different ages within the Basement Complex of the Rhodesian Archaean craton. The oldest terrain is ~ 3,500 Myr old and occurs in the southern and central parts (Fig. 1 and Table 1). Its greenstone belt remnants equate largely with the Sebakwian Group of the Rhodesia Geological Survey as delineated by Wiles². The main greenstone belts are younger and can be divided into the widespread Upper Greenstones and the more problematical Lower Greenstones which together correspond largely to the Bulawayan Group of Wiles. The Sebakwian and Bulawayan Groups as delineated by Anhaeusser³, on the basis of the Barberton model, do not correspond to those of Wiles, or to the subdivisions recognised in this paper.

The age of the Lower Greenstones is obscure. They were deformed and eroded before the deposition of the Upper Greenstones. The results obtained so far on Lower Greenstones material yield ages in the ~ 2,700 Myr bracket, but initial ⁸⁷Sr/⁸⁶Sr ratios are higher than the near 0.701 values typical of the Upper Greenstones. Whether such high initial ratios (for example 0.7056 ± 0.002, Hokonui tuffs⁴) merely reflect the primary composition of these rocks, or can be taken as evidence for metamorphic rotation of the isochron to an age significantly younger than their age of formation, is still debatable. On

ands¹ it is possible that the Lower Greenstones are granite-greenstone terrain incorporating tonalites and gneisses. For example the Mashaba tonalite and Chingezi gneisses of Belingwe) dated at ~ 2,900 Myr (Table 1; refs 4,5). Greenstones are ~ 2,700-Myr-old and the low initial ratios are consistent with this being an age of eruption⁶. To the east and the west the Upper Greenstones are overlain by the Bulawayan Group. Condie⁷ have recently offered an age of 3,080 ± 60 (errors) for the Bulawayo-Que Que greenstone belt, but might place any geological significance on this result. Geologically their data points involve a spread of 200 km and lithically they range from Lower Greenstones to the top of the Upper Greenstones. Moreover their selection of 15 points from the 50 considered, seems somewhat arbitrary.

The 3,500 Myr terrain

The development of ~ 3,500-Myr-old rocks occurs within a large triangular crustal segment with Selukwe, Fort Victoria and Anabani near the approximate corners⁸. Much of this segment consists of gneisses such as those around Shabani, and the gneisses west of Mashaba (Table 1). Most are tonalitic and highly deformed and, together with the infolded greenstone belt remnants, look like the remains of an ancient, northerly trending, mobile belt. Between Mashaba and Fort Victoria the gneisses are cut by the ~ 3,500-Myr-old Mushandike granite^{9,10} and elsewhere by younger granitic rocks¹. The greenstone belt remnants within the segment, and the presumed ~ 3,500 Myr-old remnants elsewhere in the central cratonic area (Fig. 1), consist of various sedimentary and igneous metasedimentary rocks and other mafic and ultra-mafic types. Felsic metavolcanic rocks are apparently absent, although they would be difficult to recognise within the gneisses. Outside the triangular segment it is not clear how much of the associated gneissic terrain is ~ 3,500 Myr old. The best documented of the larger areas of ~ 3,500-Myr-old

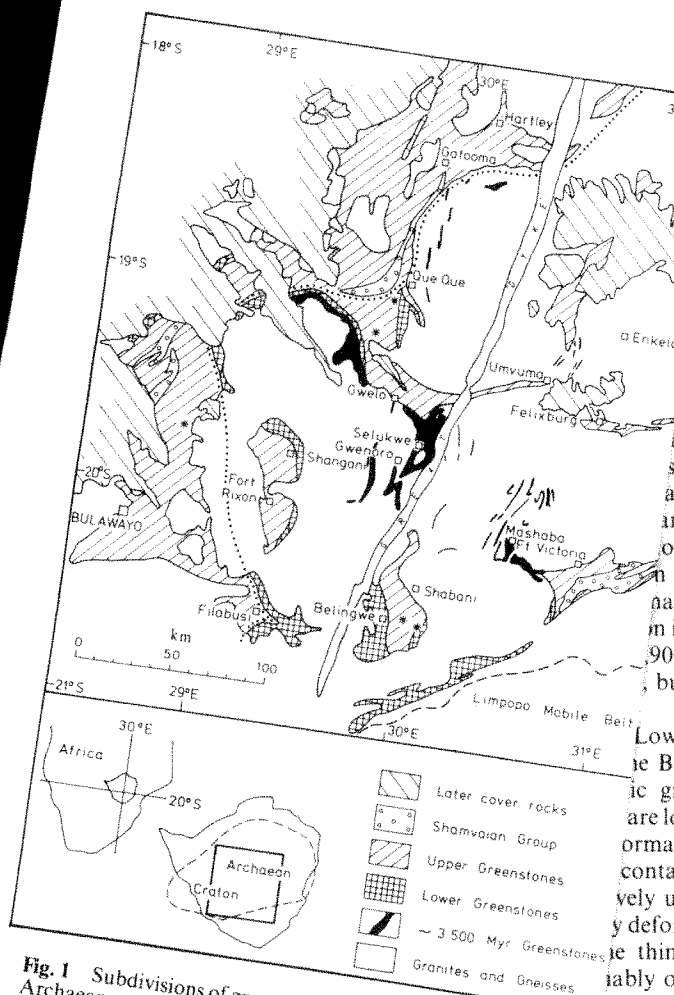

Fig. 1 Subdivisions of greenstone belts in central area of Rhodesian Archaean craton. *, Stromatolites. Dotted line represents approximate division between western and eastern successions of Upper Greenstones.

greenstone belts is the Selukwe area. Here the succession is inverted and forms the lower limb of a large recumbent structure, called the Selukwe nappe¹¹⁻¹⁵. This structure is cut by granite of the Mont d'Or formation dated at ~ 3,400-Myr-old. The rocks of the Selukwe greenstone belt are largely meta-volcanic, ranging from basaltic to peridotitic, but they also include chromitite-bearing ultramafic intrusion. About half-way up the succession is the sedimentary Wanderer formation, the conglomerate of which rests with a marked unconformity on deformed and eroded ultramafic intrusion. Boulders within the conglomerate are particularly significant since they include gneissic tonalite and granodiorite, massive adamellite and pyroxenite¹⁵, indicating the presence of complex sialic crust predating at least part of the ~ 3,500-Myr-old greenstone belts.

The ~ 2,900 Myr terrain

A major ~ 2,900-Myr-old granitic event, which was considered to represent a minimum age for the main greenstone belts, was postulated by Wilson¹⁷ on the basis of conventional K/Ar results¹⁸ from a number of granites and gneisses in the central cratonic area. Subsequent Rb/Sr work disproved this and showed these K/Ar data to be quite unreliable as indicators of age intrusion.

Two more recent Rb/Sr results^{4,5}, however, confirm the presence of ~ 2,900-Myr-old granitic rocks within the cratonic area. These rocks, which form part of the pre-Upper Greenstone basement, are the homogeneous, slightly foliated Mashaba tonalite, which effectively separates the ~ 3,500-Myr-old rocks between Mashaba and Selukwe, and the highly flattened tonalitic Chingezi gneisses¹⁹ on the west side of the Belingwe greenstone belt (Table 1). The Chingezi tonalite, lithologically similar to the Mashaba tonalite, intrudes the Chingezi gneisses and the Lower

Hokonui formation) west of Belingwe. It is so far that it may also be part of the ~ 2,900-Myr-old terrain.

greenstone belts

correlated the main stratigraphic units of the greenstone belt²⁰⁻²³ across the central cratonic area. The belt consists of two sequences, the Lower and Upper Greenstones, separated by an unconformity and by at least one episode of deformation. The Lower Greenstones flank the Upper Greenstones on the western and southeastern sides of the

central (Bend) formation, in the western development of the Lower Greenstones, consists of alternating pillowed basalts, spinifex-textured peridotites and intercalated banded gabbros, capped by a thick conglomerate member which contains an interbedded unit of felsic agglomerate. Boulders in the conglomerate include granitic types. Underlying the Bend formation is the Hokonui formation (Table 1) which consists mainly of felsic flows and pyroclasts. Below the Hokonui formation is a poorly exposed unit of amphibolites, infolded with ~ 2,900-Myr-old Chingezi gneisses. The status of this unit is uncertain, but we have included it with the Lower Greenstones in

the Lower Greenstones on the south-east side of the Belingwe greenstone belt (the Brooklands formation) pass upwards from quartzites, gabbros, granitic grits and conglomerates into high-magnesium lavas which are locally pillowed and alternate with phyllites and banded gabbros. The conglomerates contain tonalite clasts. The contact of the Brooklands formation is not exposed, but its position is indicated by undeformed greenschist facies rocks abut on to completely deformed ~ 3,500-Myr-old gneisses⁵. The thin Manjeri formation forms the base of the unconformably overlying Belingwe Upper Greenstones. It consists of thin developments of clastic shallow water sediments and lime-stones, capped by a persistent horizon of predominantly sulphide-bearing banded iron-formation. On the west side of the belt the Manjeri formation lies on Lower Greenstones; on the east side, it passes into the Brooklands formation to lie with well-exposed Upper Greenstones in conformity on the ~ 3,500-Myr-old Shabani gneisses^{20,21}. Above the Manjeri formation is a thick tholeiitic volcanic sequence of massive and pillowed basalt and metabasalt flows with

Table 2 Simplified western and eastern successions of the Upper Greenstones¹

Western succession	Eastern succession
Calc-alkaline suite of basalt, andesite, dacite flows and pyroclasts; some mafic sills. (? ± 4 km thick)	Not developed
Bimodal volcanic suite: tholeiitic and magnesium-rich basalt and metabasalt pillowed and massive flows, some peridotites; alternating with dacitic flows, tuffs and agglomerates. Grits and conglomerates locally derived from pyroclasts. Sericitic schists. Mafic sills; banded iron-formation phyllites, local limestones in places stromatolitic. (? ± 4 km thick)	Tholeiitic and some magnesium-rich basalt and metabasalt pillowed and massive flows. (? 1–2 km thick)
As for eastern succession	Phyllites, banded iron-formation, local conglomerates and grits; some limestones in places stromatolitic. (Up to 2 km thick)
As for eastern succession	Tholeiitic basalt and metabasalt pillowed and massive flows. Basal development of peridotitic and magnesium-rich basalt flows. Subsidiary sills. Minor pyroclasts. (Up to 7 km thick)
As for eastern succession	Banded iron-formation, local conglomerates and grits, some limestones in places stromatolitic. (Up to 0.25 km thick)

some high-magnesium basalt and subsidiary sills, the whole largely devoid of sediments. The lowermost part of this volcanic sequence is dominated by high-magnesium rocks including pillowed and spinifex-textured peridotite flows and is known as the Reliance formation; the thicker, major part is the Zeederbergs formation^{20,24}. Capping the Zeederbergs formation are the dominantly pelitic shallow-water sedimentary rocks of the Cheshire formation, with locally developed banded iron-formation and limestone.

Figure 1 shows the distribution of the Lower and Upper Greenstones in the central cratonic area¹. Detailed comparisons within the Lower Greenstones are difficult but elements of the Belingwe succession can be recognised. Prominent in all occurrences west of the Great 'Dyke' is a thick unit of Hokonui-type felsic volcanic rocks and derived schists, whereas the linear Mweza greenstone belt²⁵, south-east of Belingwe, contains a sequence possibly transitional between the Bend and Brooklands formations. North-west of Gwelo the Lower Greenstones lie with marked unconformity (refs 1, 26 and D. Edwards personal communication) on presumed ~ 3,500-Myr-old greenstones; elsewhere their lowest preserved sequences are intruded by granitic rocks.

Correlations¹ for the Upper Greenstones in the central cratonic area are, however, clearer. In much of the southwestern part of the area, covered by Fig. 1, the base of the Upper Greenstones is indicated by a thin Manjeri-type marker unit which can be traced for many kilometres and from greenstone belt to greenstone belt. This is succeeded by a thick Zeederbergs-type volcanic pile which is conspicuous in all the major greenstone belts and equates with the basaltic greenstones of Macgregor's Bulawayan System^{27,28}. In several areas the basal part of this succession is a high-magnesium Reliance-type volcanic assemblage. Thereafter, however, above this total volcanic pile the succession in the eastern central cratonic area differs from that in the west¹.

In the east the volcanic pile is capped by Cheshire-type sediments, which are overlain by, and in part interbedded with, a further development of tholeiitic lavas not seen at Belingwe. In the west the thick basaltic pile passes up into repeated bimodal mafic-felsic volcanism on different scales in which tholeiitic and in places high-magnesium spinifex-textured (basaltic and peridotitic) flows alternate with felsic flows and pyroclasts. Sediments derived from the felsic rocks, as well as banded iron-formation and a few limestones, are also a feature of this bimodal succession. Where metamorphosed and deformed, the felsic rocks are sericite schists. Wilson¹ has shown that the western bimodal succession is the time equivalent of, and can be traced laterally into, the eastern pelite-dominant sedimentary unit and its overlying basalts. Suc-

ceeding the bimodal pile is an andesite-dominant, calc-alkaline volcanic assemblage, ranging from basalt to dacite, which was not developed in the east. These two upper western units are confined to a broad zone trending approximately north-north-east across the central cratonic area. In the Que Que and Gatooma areas the bimodal succession includes most of the loosely defined Felsic formation of Harrison^{29,30} and Bliss³¹, whereas the calc-alkaline assemblage embraces the Maliyami formation (Table 1) and the Umniati group respectively of these two authors.

J.F.W.'s¹ correlations across the greenstone belts also allow the rationalisation of the known occurrences of Rhodesian Archean stromatolites which now number five (Fig. 1). All of these occur in the Upper Greenstones. Two occur in limestones of the basal formation below the thick tholeiitic pile; one at Belingwe²⁰, and one at Redcliff south of Que Que (C. A. Castelin, personal communication). Three occur in limestones above the thick tholeiitic pile; one at Belingwe²⁰, one south-east of Redcliff (C. A. Castelin, personal communication) and one, the Huntsman limestone stromatolites of Macgregor³², some 60 km north of Bulawayo.

Table 2 summarises the western and eastern successions of the Upper Greenstones. Figure 2 shows their most likely distribution in the craton as a whole^{1,33,34}.

The Shamvaian Group unconformably overlies the Upper Greenstones in the west, east and south-east of the craton¹. The characteristic main rock types are arkoses and sub-greywacke types, rapidly deposited in shallow water and derived from a mixed granitic-volcanic terrain.

Late granites and mafic-ultramafic intrusions

Two suites of late granitic rocks can be recognised post-dating the Upper Greenstones and the Shamvaian Group (Fig. 3). The Sesombi Suite¹ of tonalites and associated granodiorites occurs in the west parallel to the north-north-east trending line of the upper units of the western succession of the Upper Greenstones. The ~ 2,700 Myr ages and the low initial ⁸⁷Sr/⁸⁶Sr ratios of the Sesombi and Somabula tonalites, the two members of the suite so far dated, are indistinguishable from those obtained from the (Maliyami) calc-alkaline volcanic rocks themselves (Table 1). The two intrusions, and by analogy the whole suite, can be regarded as late plutonic expressions of the same magmatic episode which produced the andesites and dacites of the calc-alkaline assemblage. The low initial ratios preclude sources for these volcanics rocks and tonalites in remelting of earlier granite-gneiss terrain^{4,6,35}.

The later ~ 2,600-Myr-old Chilimanzi Suite of intrusions (Table 1) constitute the last major pre-Great 'Dyke' granitic event

Fig. 2 The main greenstone belts of the Rhodesian Archean craton with the Great 'Dyke' and its associated intrusions and major fractures. (1) Umvimeela Dyke; (2) Great 'Dyke'; (3) East Dyke; (4) Popoteke Fault. The dotted line indicates the division between the western and eastern successions of the Upper Greenstones.

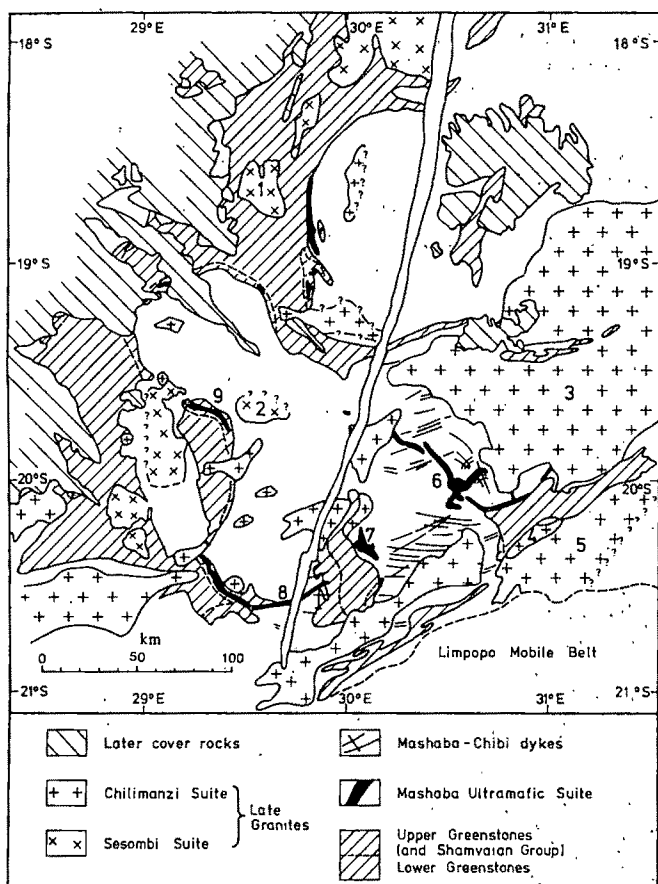

Fig. 3 Distribution of late granites, Mashaba-Chibi dykes and Mashaba Ultramafic Suite in relation to the main greenstone belts in central area of Rhodesia Archaean craton. 1, Sesombi tonalite; 2, Somabula tonalite; 3, Chilimanzi batholith; 4, Victoria Porphyritic granite; 5, Zimbabwe batholith; 6, Mashaba Igneous Complex; 7, Shabani intrusion; 8, Gurumba Tumba-Filabusi intrusion; 9, Shangani intrusion.

in the craton. Petrologically the rocks are dominantly adamellites with local development of granodiorite. The intrusions occur across the craton, but are particularly extensive in the southern and eastern parts. In the southern part of the craton in particular, the intrusions show an east-north-east trend parallel to the Limpopo mobile belt. The strontium isotope data available are compatible with an origin for the Chilimanzi Suite in the remelting of earlier sialic crust^{1,4,36}.

The Mashaba Ultramafic Suite of layered intrusions, together with certain dyke swarms collectively termed the Mashaba-Chibi dykes (Fig. 3), are considered to be broadly contemporaneous with the thick tholeiitic (and high-magnesium) pile which forms the lower part of the Upper Greenstones. None of the intrusions or dykes has yet been dated, but available field evidence places them clearly between the Chilimanzi Suite (~ 2,600 Myr) and the ~ 2,900-Myr-old granitic terrain; they are apparently confined to rocks which pre-date the Upper Greenstones.

The best-documented of the layered intrusions are those of Mashaba and Shabani³⁷⁻⁴⁰, which cut the crustal segment containing the major development of ~ 3,500-Myr-old rocks. The major development of dyke swarms is also within this segment. Some constitute a modified ring and radial pattern and are late phases of the Mashaba Igneous Complex^{37,38}; others are later than the radial swarms and strike east-north-east. The dykes and the Mashaba Igneous Complex also intrude the Mashaba tonalite in this crustal segment.

To the west, dykes and the Gurumba-Tumba Filabusi intrusion cut the Lower Greenstones (Hokonui formation) of the Belingwe belt as well as the Chingezi tonalite and gneisses^{19,23}. North-west of Shangani an undated stock of Sesombi-Suite type truncates the Shangani intrusion¹.

Discussion

The Rhodesian Archaean craton contains granitic rocks intruded during at least three separate events ~ 3,500 Myr, ~ 2,900 Myr and 2,700–2,600 Myr. The ~ 3,500-Myr and the 2,700–2,600-Myr-old events are both associated with greenstone volcanicity and sedimentation. The ~ 2,900-Myr event may well be associated with the Lower Greenstones, if the Chingezi gneisses and Mashaba-type tonalites represent plutonism complementary to the Lower Greenstones felsic volcanicity.

The status of the Gwenoro and Umniati River gneisses is still obscure. They give ages younger than 2,900 Myr ($2,780 \pm 60$ and $2,760 \pm 80$ Myr, Table 1). The Mashaba Ultramafic Suite and the Mashaba-Chibi dykes serve largely to delineate the pre-Upper Greenstones basement. In neither of these two areas of gneisses, however, have representatives of these intrusions or dykes been recognised. Thus these gneisses could be related to an early phase of the ~ 2,700 Myr-old Sesombi Suite. Alternatively they could equally represent a late stage of tonalitic plutonism complementary to the Lower Greenstones, since Stowe's¹¹⁻¹³ mapping supports a pre-Upper Greenstones age for the Gwenoro area gneisses.

The stratigraphic correlations proposed by J.F.W.¹ emphasise that the Upper Greenstones are the remains of a widespread cover sequence which was subsequently deformed to give, very largely, the present configuration of the main greenstone belts. There is now clear evidence of an extensive basement to this Upper Greenstones cover. This basement consisted of the ~ 3,500-Myr-old granite-greenstone terrain, gneisses and tonalites intruded at ~ 2,900 Myr, the Lower Greenstones, and possibly gneisses dated at ~ 2,800 Myr. Remnants can be seen as far east as the (pre-Mushandike granite) gneisses near Fort Victoria, to the Lower Greenstones on the west side of the greenstone belt north of Bulawayo, and east of Que Que (Fig. 1).

The two differing volcanic provinces recorded in the Upper Greenstones would, on any modern analogy, correspond to the constructive and destructive phases of a plate cycle. Perhaps some of the closest modern analogues to the basal sedimentary and volcanic formations are in rifted continental areas, such as Svartenhuk in west Greenland and the Karoo Super Group in southern Africa. Perioditic lavas are apparently restricted to the Archaean, but these younger rifted areas do contain high-magnesium basalts at the base of thick, near sediment-free, piles of basaltic volcanics^{41,42}. What is not clear, however, is whether a tectonic regime responsible for rifting in the Archaean also produced major ocean basins elsewhere, as happened in these Phanerozoic examples.

The present areal distribution of volcanic rocks in the younger parts of the Upper Greenstones, on the other hand, is reminiscent of modern destructive continental margins (Fig. 1); the true western extent of the calc-alkaline suite is obscured by younger rocks, but on present exposures there is a characteristic linear distribution. It is debatable, however, whether this necessitates an origin in a regime analogous to present-day plate tectonics involving subduction. Hawkesworth and O'Nions³⁵, for instance, point out that, in marked contrast to modern plate margin examples, the tholeiites and calc-alkaline rocks of the Upper Greenstones have trace element characteristics which suggest derivation from chemically similar sources. They favour rifting within a continental block for both rock suites which is compatible also with the wide extent of the pre-Upper Greenstones basement as now established. Nevertheless it is intriguing that if a plate tectonic model is adopted, the Upper Greenstones could record both the creation and subsequent destruction of an Archaean ocean basin.

In considering rifting models it is interesting to observe the re-occurrence through time of a near north-northeasterly trend in the Rhodesian Archaean. This is the tectonic trend of the Upper Greenstones, in particular the calc-alkaline suite; it reflects the fundamental grain of the ancient ~ 3,500-Myr-old rocks; and is seen again in the ~ 2,900-Myr-old Mashaba tonalite. More significantly perhaps it is the trend of the Great 'Dyke' fracture system¹. This includes the line of layered mafic-ultramafic

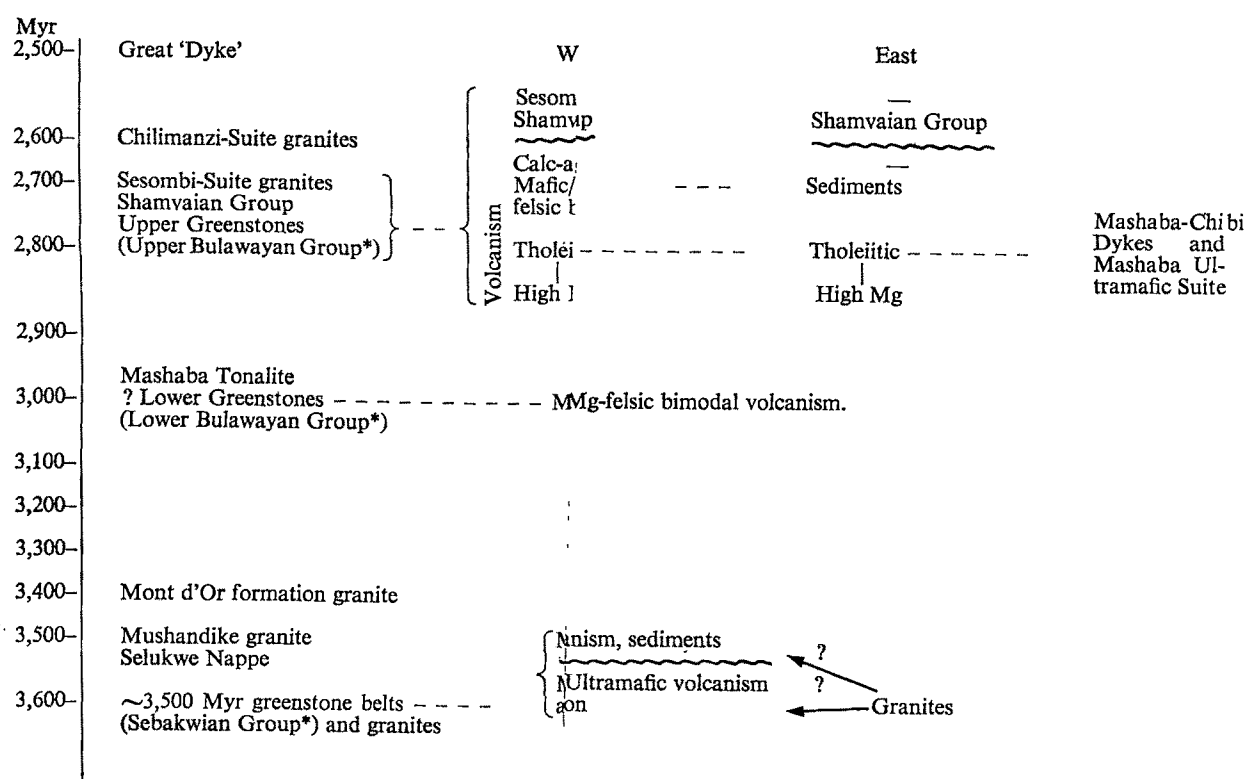

Fig. 4 Summary of major events in the Rhodesian Archaean. *, Nearest equivalent in Rhodesia Geological Survey terminology.

intrusions which constitute the Great 'Dyke' itself⁴³—vimeela and East (true) dykes; and a number of pre-sinistral wrench faults of which the Popoteke fault is the best example (Fig. 2).

Pretorius (in ref. 44) has suggested that the Great 'Dyke' formed in a fracture system which developed in the region of the Rhodesian craton during movements in adjacent belts. Katz⁴⁵ has proposed that the Limpopo mobile belt is a transform zone which, during its initiation, developed greenstone belts on the Rhodesian and Kaapvaal cratons in the system at high angles to it, with subsequent reactivation of the transform zone to produce the rift of the Great 'Dyke'.⁴⁶ We have looked to large intracratonic block movements in deformation in the Limpopo belt and within the Archaean craton.

Accepting a rifting model for the initiation of the Greenstones, and bearing in mind that these ~ 2,700 Myr rocks have not been recognised south of the Limpopo belt, the Kaapvaal craton, it seems reasonable also to accept for intracratonic block movements across what is now the Limpopo mobile belt (and perhaps even also involving a sub-part to the north¹) were accompanied by craton-wide fracturing. An approximately north-north-east trend confined to the Limpopo block, which was effectively the pre-2,700 Myr craton, so that intracratonic block movements, whatever might be their fundamental causes, have been operative over the degrees of intensity from about 2,700 Myr to 2,500 Myr. The Lower Greenstones had an origin in similar earlier events, and some of the Limpopo gneisses are ~ 2,900-Myr. The period is possibly 3,000 Myr to 2,500 Myr. By 2,500 Myr the Rhodesian block, finally stabilised by the wide Chilimanzi-Suite of late granites, fractured sufficiently to form the Great 'Dyke' pattern; and thus, in the Great 'Dyke', the magma of which was some kind of magnesium-rich^{48,49}, we are perhaps seeing a last abortive attempt at an Archaean greenstone belt^{1,50}.

Figure 4 summarises the major events in the development of the Rhodesian Archaean craton.

Direct comparison of theoretical and experimental melting profiles for RFI Φ X174 DNA

Y. L. Lyubchenko, A. V. Vologodskii & M. D. Framenetskii

Department of Biology, I. V. Kurchatov Institute of Atomic Energy, Moscow, USSR

The determination by Sanger et al. of the complete nucleotide sequence for Φ X174 DNA has made it possible for the first time to compare directly theoretical and experimental DNA melting profiles. The comparison shows that the theory predicts the observed shape of the differential melting curve surprisingly well. Calculation of the denaturation maps allows the peaks on the curve to be correlated with co-operative melting out of concrete regions on the sequence of nucleotides.

HELIX-coil transition or intramolecular melting of the DNA double helix has been studied extensively both experimentally and theoretically for many years (see refs 1-4 for reviews). Until recently the DNA melting curve was thought to reflect rather rough characteristics of base-pair distribution and by the use of it a DNA sequence could be placed only into one of the two categories—quasirandom or block-quasirandom (see refs 1, 2). Recently, however, the viral DNA melting curves have been shown to exhibit a clear-cut fine structure which reflects specific DNA sequences to a much greater extent⁴⁻¹⁰. This fine structure manifests itself most clearly when a derivative of the degree of denaturation with respect to temperature, or differential melting curves, are plotted. Such a plot for a sufficiently short genome consists of a series of sharp peaks with half-width of about 0.3° (see refs 5-10).

There has been considerable progress in the construction of a theory of helix-coil transition in DNA. The theory predicts correctly the main overall characteristics of the process—the melting range width, the number of bases in alternating helical and coiled sections within the melting zone and others. Moreover, the theory has succeeded in predicting the effect of fine structure of the differential melting profiles^{4,5,11}. Sequences in these calculations were simulated with the aid of a generator of random digits because of the lack of data on nucleotide sequence for any DNA: this prevented the direct comparison between the theory and experiment. The situation has changed now that Sanger *et al.*¹² have published the complete nucleotide sequence for Φ X174 DNA. In the present work we are using these data to compare directly, for the first time, theoretical and experimental differential melting profiles.

Recent advances in theory

A model that is used in the theory of helix-coil transition is rather simple (see refs 1-4 for reviews). Each base pair is assumed to belong to one of the two states—'helical' or 'coil-like'. Opening of a base pair at the end of a helix needs free energy ΔF_{AT} for an AT pair and ΔF_{GC} for a GC pair. Formation of a new unwound region inside the helix needs an additional energy, F_s , that may be considered as the energy of base-pair stacking. In addition to these ordinary features of the well known Ising model, the DNA model includes so-called loop-weighting factors. These statistical weights appear because unwound regions in DNA have the shape of a closed polymer chain.

Comparison of theoretical and experimental melting profiles

Closed circular double-stranded replicative form (RFI) of Φ X174 DNA is not of interest for our purposes because both theoretical

Fig. 1 (a) Experimental and (b) theoretical differential melting profiles of RFI Φ X174 DNA in 0.1SSC. The theoretical curve was calculated using the sequence of nucleotides determined by Sanger *et al.*¹² and the theory of helix-coil transition in DNA using the standard parameters^{1,2,4,5,18}: $\sigma = 5 \times 10^{-5}$; $\alpha = 1.5$; $U_{AT} = -1$, $T_{AT} = 52.5^\circ\text{C}$; $T_{GC} - T_{AT} = 42.4^\circ\text{C}$. Replicative form (RFI) of Φ X174 DNA was obtained from the cells of *Escherichia coli* infected by phage Φ X174, the multiplicity of infection 10, with subsequent treatment by chloramphenicol. The Φ X174 of wild type and *E. coli* C cells were gifts of Drs E. S. and L. Patrushev. The chromosomal DNA was removed by centrifugation (40,000g, 1 h) and the supernatant was suspended in 50% isopropanol. The separation of RFI DNA mixture of RFI and the linear DNA molecules was done by centrifugation in density gradient of CsCl with addition of ethidium bromide (200 $\mu\text{g}/\text{ml}^{-1}$)²². Ethidium bromide was removed by isopropanol extraction and subsequent dialysis against SSC buffer (0.15M NaCl, 0.015M Na citrate). The sample contained about 90% of RFI DNA and 10% of R. Conversion of RFI DNA into RFII DNA was done using nuclease¹⁹ in 0.2M CH_3COONa , pH 4.6 in the presence of ZnSO_4 at 37°C ; sufficient enzyme was added to half of the DNA (5 $\mu\text{g}/\text{ml}^{-1}$) in 10 min. The reaction was followed by appearance of RFI band in the course of Agarose gel electrophoresis. Incubation for 30 min led to the complete disappearance of RFI DNA. At the same time about 10% of the molecules were converted into linear form. Melting of DNA was followed by appearance of RFI band in the course of Agarose gel electrophoresis. Incubation for 30 min led to the complete disappearance of RFI band. Differential melting profiles were obtained by graphical differentiation and automatically²³. The profiles obtained by the two methods and in many independent measurements were very close. The filled and open circles on the experimental curve (a) are two examples of such measurements. The long plateau at high temperatures represents contamination, probably due to host DNA.

predictions and experimental observations led to the conclusion that such DNA molecules should have broad but structureless differential melting profiles⁵. So theoretical calculations and experimental investigations should be conducted in RF II DNA having a single-stranded break (nick).

We have converted RF I DNA into RF II using S1 endonuclease. This enzyme was shown by Kato *et al.*¹⁹ to introduce the nicks into RF I Φ X174 DNA by a random way. The theoretical profile was obtained by averaging over ten calculated curves differing one from another by a position of nick. The shape of the theoretical differential melting profile depends on the position of the nick but this dependence is not strong—the peaks are shifted by not more than by 0.1–0.2 °C.

Theoretical and experimental differential melting profiles thus obtained are given in Fig. 1. In general, the curves are remarkably alike. Indeed, positions of peaks at 70.4, 70.9, 71.0 and 72.6 °C coincide for theoretical and experimental profiles with as high precision as of about 0.1 °C. But the amplitudes of the peak at 72.6 °C are very different for both curves and, beginning with this peak, the curves differ from one another considerably. We shall discuss the possible causes of these discrepancies (below).

Correlation of theoretical denaturation maps with melting profile

In addition to the melting profile, the theory permits the calculation of a denaturation map, that is, the dependence of the probability of a base pair to be open on its position within a nucleotide sequence.

Figure 2 shows theoretical denaturation maps calculated for RF II Φ X174 DNA in different temperatures. Values of the temperature are indicated to the right. These maps being compared with the differential melting profile presented in Fig. 1 enable us to correlate the peaks on the profile with co-operative melting of concrete regions on the nucleotide sequence published by Sanger *et al.*¹².

Until recently a rigorous and effective algorithm for calculating a melting curve for DNA with an arbitrary sequence of base pairs has been lacking. Such an algorithm has now been formulated as the result of the following sequence of events.

Lacombe and Simhar¹³ developed the unique probability formalism allowing the calculation of equilibrium characteristics for a linear heterogeneous system. This formalism was different from, but equivalent to the ordinary formalism based on the partition function method. Poland¹⁴ showed that this formalism made it possible to treat rigorously the DNA model. By the method of Poland, and the previously proposed method of Wartell and Montroll³ based on ordinary formalism, were not sufficiently effective—the computer time required was proportional to N^2 where N is the number of base pairs in the chain. An approximate method¹⁵ was proposed as early as 1969 for which the computer time is proportional to N . This method has been used extensively in this laboratory^{1,2,5}. Recently Lukashin *et al.*¹⁶ have compared the results of calculations by this method with the results obtained by the exact methods^{3,14} and concluded that the approximation¹⁵ gives results which are in accord with results of exact methods. These findings stimulated Fixman and Freire¹⁷ to introduce an idea that formed the basis of the method¹⁵ into formalism^{13,14}.

Fixman and Freire¹⁷ succeeded in formulating an exact algorithm for which computer time is proportional to the number of base pairs in DNA. So now, at last, theoreticians have an exact and highly effective method¹⁷ for treating the DNA model. This method is used here to calculate differential melting profiles and denaturation maps for RF II Φ X174 DNA.

Parameters of the theory

The theory of helix-coil transition makes it possible to compute a melting curve and a denaturation map for DNA if a sequence of base pairs and values of parameters of the theory are given. The theoretical parameters are as follows (see refs 1–4): the melting enthalpy for an AT pair, U_{AT} ; the melting temperature of

Fig. 2 Theoretical denaturation maps for RF II Φ X174 DNA calculated with the same set of parameters as indicated in the legend for Fig. 1. As for the melting profile, each map was obtained by averaging over ten maps differing from one another by the position of the nick. The sequence is numbered as in Fig. 1 of ref. 12. An ordinate presents the probability of a base pair to be open averaged over 25 subsequent base pairs.

poly AT; T_{AT} ; the difference $T_{GC} - T_{AT}$; the co-operativity factor, σ ($\sigma = \exp(-F_s/RT)$); and loop-weighting exponent α .

The value U_{AT} has been determined from calorimetric and other data and it is equal to 8.0 kcal/mol (see, for example, ref. 4). The values of T_{AT} and $T_{AT} - T_{GC}$ depend on ionic conditions and are determined from a series of experiments with DNA having different GC content. For conditions used in the present work (0.1SSC), $T_{AT} = 52.5$ °C and $T_{GC} - T_{AT} = 42.4$ °C, see ref. 18.

The value of σ is chosen as a rule to be equal to 5×10^{-5} and $\alpha = 1.5$ (see refs 1,2,4,5). A considerable ambiguity exists in this choice of values—the value of $\alpha = 1.8$ is more justifiable from the theoretical point of view than the value of 1.5 and that of σ is not known more accurately than to within an order of magnitude. Fortunately, as appropriate calculations have shown, the differential melting profile, at least in our case, is practically unaffected by the change of these two parameters within the limits of their possible variations. In general, our calculations show that the shape of differential melting curve is highly sensitive to the sequence of base pairs and to the values of parameters U_{AT} and $T_{GC} - T_{AT}$ but insensitive to the particular values of the rest of parameters.

The regions melting at the lowest temperatures are too short to give distinct peaks on the differential melting profile. Nevertheless the shoulder at 69.3 °C may be recognised on the theoretical profile originating from the melting out of the region, which is situated, as one may conclude from Fig. 2, between bases with order numbers 25 and 100. Inspection of the corresponding piece of the nucleotide sequence¹² shows that this region is highly enriched (by about 20%) by AT pairs as compared with the sequence as a whole.

The first distinct peak at 70.4 °C appears mainly due to a co-operative melting of the region situated between 3.80 and 4.00 kilobases. Then the two neighbouring regions situated at 3.35–3.80 and 4.00–4.30 kilobases are melting out simultaneously giving the large peak at 70.9 °C. The main peak at 71.7 °C originates from a co-operative melting of the very large region containing about 850 base pairs situated between 1.40 and 2.25 kilobases. Simultaneously the region between 4.30 and 4.65 kilobases melts. The melting of this region that may explain, at least in part, the peak at 72.0 °C on the experimental profile. Indeed, such a peak, but with much lower magnitude than the experimental one, appeared on theoretical profiles for some positions of the nick.

The large peak at 72.6 °C on the theoretical profile corresponds to a simultaneous melting of two independent regions at 2.90–3.35 and 4.65–4.95 kilobases. Finally the last small peak on the theoretical profile originates from the melting of the region positioned between 1.00 and 1.15 kilobases. The small area which remains completely helical up to the highest temperature is situated, as it can be seen from Fig. 2, at 0.87–0.90 kilobases. Inspection of the nucleotide sequence¹² in this site shows that starting from 872-th nucleotide the sequence of 35 bases highly enriched by GC pairs follows. It contains only 8 AT pairs and it has higher GC content, compared with the mean value, by more than 25%. This GC cluster remains completely helical up to about 73.5 °C.

It should be remembered in this connection that the theory of helix-coil transition in DNA used here is valid under the assumption that complete dissociation of complementary strands does not take place. This assumption is valid until a single helical region exists, that is, up to about 73.5 °C, for our particular case, and it fails for higher temperatures. So, at best, accordance between the theory and experimental results may be expected only for the temperatures lower than 73.5 °C. We can conclude that the only serious difference between the theoretical and experimental melting profiles is the too large a magnitude of the peak at 72.6 °C on the theoretical curve. Indeed the melting of the region situated between 0.50 and 0.85 kilobases (see Fig. 2) should give a peak at 72.8 °C, which may be considered as corresponding to the peak at 73.0 °C on the experimental curve. On the theoretical curve (see Fig. 1) it is masked by a powerful peak at 72.6 °C.

It should be emphasised that in general it is absolutely impossible to predict, just by inspecting a sequence of nucleotides, what particular region would melt out co-operatively to result in a peak on the differential melting profile. Only for two extreme regions, highly enriched by AT pairs and highly enriched by GC pairs, does the simple explanation of their behaviour, given above, exist, but these sequences are too short to give a distinct peak on the profile. For the rest of the sequence it is only the theory of helix-coil transition in DNA that makes it possible to indicate the regions which are melting out co-operatively and to correlate them with peaks on the differential melting curve.

Note also that the melting temperature of a region depends not only on its GC content but also on its length and boundary conditions. For example, the region at 0.50–0.85 kilobases contains about 47% GC, the region at 4.65–4.95 kilobases contains about 50% GC but the former melts at a slightly higher temperature than the latter in contrast to the expectation based only on their GC content. The causes are clear—the region at 0.50–0.85 kilobases had a melted area only to its left before melting, but the region 4.65–4.95 kilobases had the melted areas from both sides. Thus considerable errors may follow from an attempt to correlate

Fig. 3 Theoretical (c, d) and experimental (a, b) differential melting profiles for reaction fragments Y_1 (a, c) and Y_2 (b, d) of $\Phi X174$ DNA in a 0.1 M aqueous solution. Experimental profiles are taken from Wada *et al.*²⁷. Solid and dotted curves correspond to different experiments and demonstrate reproducibility. Theoretical curves were calculated using the parameters listed in Fig. 1 legend.

directly the position of a peak on a differential melting curve with GC content of a corresponding region.

Possible causes of discrepancy

The above discussion shows that the only important discrepancy between the theoretical and experimental melting profiles is the difference of magnitudes of the peak at 72.6 °C for both curves. Special calculations excluded an ambiguity in the values of parameters σ and α as a possible cause of this difference. Two causes that may be responsible for it are discussed below.

First the real sequence of nucleotides in the DNA studied by us experimentally may differ from the sequence published by Sanger *et al.*¹². The phages used by Sanger *et al.*¹² and by us are of different origin but they probably differ from one another by only a few point mutations. Possibly of more importance, however, as Sanger *et al.*¹² emphasised, occasional errors might be introduced into the sequence during the laborious experiments involved in the determination. The regions where such errors may occur are shown in Fig. 1 of their paper¹². In the four positions the bases are not indicated at all. We have filled these gaps in the following way: 1,421, A; 1,422, A; 1,423, C and 1,657, C. These few uncertainties cannot affect the results presented above. But our results may be influenced by the fact that a very long region exists starting at 2.95 and extending to 3.68 kilobases where one mistake

per 50 residues, and in some places even greater level of uncertainty, is possible. Indeed, one of the regions contributing to the peak at 72.6 °C on the theoretical curve in Fig. 1, the region 2.90–3.35 kilobases, is situated almost completely within this most uncertain area. Note that most of the theoretical profile presented in Fig. 1 cannot be changed because it is formed by the melting of sequences fully confirmed.

Second, the effect of heterogeneity of stacking interactions between base pairs neglected in the theory, may influence the results. This effect is large for RNA helices according to available data²⁴. But, in the case of DNA this effect is shown to be very small by direct experimentation with DNA²⁵ as well as by the theoretical analysis²⁶ of experimental data on melting of synthetic polynucleotides with known sequences. The above results show the theory to be successful in precisely predicting positions of a series of the peaks on the differential melting curve for Φ X174 DNA; this constitutes evidence for a neglected role of the effect of heterogeneity of stacking interaction. Nevertheless, we cannot yet exclude completely a possibility that in some special situations this effect may give an appreciable contribution.

It is difficult to draw an unambiguous conclusion from this work because of the possible errors in the published sequence. Nevertheless the results obtained strongly suggest that the theory can efficiently predict the shape of a differential melting curve in detail. The model which forms the basis of the theory is thus appropriate to real DNA.

We thank Dr A. V. Lukashin for help, Drs Y. S. Lazurkin and V. I. Ivanov for discussions, Mrs V. N. Syomushkina for technical assistance and Dr M. Fixman for sending a preprint of his paper.

After completion of this study we became acquainted with the very interesting data of Wada *et al.*²⁷. These authors measured

the differential melting curves for two restriction fragments of Φ X174 DNA: Y₁ consisting of 2,745 base pairs (position 3,360–729) and Y₂ consisting of 1,690 base pairs (position 1,104–2,793). We have calculated the theoretical melting profiles for these fragments which are presented in Fig. 3 along with the experimental profiles taken from ref. 27.

Comparison of amino acid sequence of troponin I from different striated muscles

J. M. Wilkinson & R. J. A. Grand

Department of Biochemistry, University of Birmingham, PO Box 363, Birmingham, UK

The sequence of troponin I from fast and slow skeletal and cardiac muscle shows strong homology in the region which binds to actin and is responsible for inhibition of the actomyosin ATPase. More differences are found in the N-terminal region which binds to troponin C.

CONTRACTILE activity in vertebrate striated muscle is regulated by the level of free Ca²⁺ in the sarcoplasm by means of the molecular switch formed by the troponin complex and tropomyosin. Troponin is composed of three components, troponin I, which inhibits the actomyosin ATPase, troponin C, which binds Ca²⁺ and troponin T, which binds to tropomyosin and locates the complex at a repeat of 385 Å along the thin filament^{1,2}. Troponin I will inhibit the actomyosin ATPase on its own but this inhibition is greatly enhanced in the presence of tropomyosin³. The inhibition is neutralised by troponin C and the restoration of full Ca²⁺ sensitivity requires troponin T^{4,5}. Each component of the thin filament can be shown to interact with two others to bring about this regulation and it has been shown that troponin I interacts with both actin⁶ and troponin C⁷, this latter interaction being Ca²⁺ sensitive. The primary structures of all the major thin filament proteins from rabbit fast skeletal muscle are known^{8–12} but while the pattern of regulation in the other major types of vertebrate striated muscle seems similar, the troponin components have been shown to differ in different muscle types^{13–15} and this may well reflect modifications in

regulatory activity. We have determined the amino acid sequence of four troponin I proteins from different sources in order to investigate the molecular basis of the interaction with the other thin filament proteins, troponin C and actin, and also to elucidate the differences between proteins obtained from different types of striated muscle. The sequences of three of the proteins chosen, fast¹¹ and slow¹⁶ skeletal and cardiac¹⁷ troponin I from the rabbit, have been published and we report here the sequence of troponin I from chicken fast skeletal muscle. A detailed description of the determination of this sequence will be published elsewhere.

Primary structure determination

The amino acid sequences of the four proteins are shown in Fig. 1. The four sequences have been aligned to give maximum homology and it will be seen that a number of deletions have to be introduced into each sequence. The numbering of the residues is that for the cardiac protein, which includes two deletions at positions 181 and 182. One correction must be made to the previously published sequence of the rabbit fast muscle protein¹¹. The sequence in the region 139–143 was previously thought to be Leu-Arg-Arg-Arg-Val but has now been shown to be Leu-Arg-Arg-Val. The corresponding sequence in the rabbit cardiac protein is Leu-Arg-Leu-Arg-Val, this was noted previously¹⁷ to be in some doubt but efforts to clarify this sequence were unsuccessful. A blocked N-terminus was found in each protein.

Fig. 1 Alignment of the amino acid sequences of troponin I from chicken fast muscle (C.F.), rabbit fast muscle (R.F.), rabbit slow muscle (R.S.) and rabbit cardiac muscle (R.C.). The complete sequence of rabbit fast muscle troponin I is presented, gaps in the other sequences indicate identity with this sequence. Residues which are identical in all four sequences are shown in capitals. Solid lines represent deletions. X indicates an unknown blocking group.

In the rabbit fast muscle protein this has been shown to be an acetyl group¹¹ and this is likely to be the case for the other proteins as all other myofibrillar proteins so far studied have been shown to be N-acetylated. One curious feature of the rabbit slow muscle protein is that although some of the molecules have a blocked N-terminus, most have proline with a free imino group and we believe this to be the first example of a myofibrillar protein with a free N-terminus. Heterogeneity was also found at the C-terminal

end of the molecule where a proportion of the molecules lacked the terminal Ser-Gln dipeptide. The origin of these different forms of slow muscle troponin I is not clear, but as the protein was isolated by affinity chromatography after extraction of muscle with 9 M urea it is unlikely that they are an artefact of preparation. Two other myofibrillar proteins, the A1 and the 'phosphorylatable' light chains of myosin^{18,19}, have been shown to have a blocked N-terminal proline, but in both cases blocking seemed to be complete.

Comparison of sequences

The four complete troponin I sequences have been compared by calculating the percentage difference between pairs of proteins (Fig. 2). As the proteins differ slightly in length, extra residues at either the N- or C-terminus were ignored and deletions were treated as an extra amino acid. The proteins were also divided arbitrarily between residues 119 and 120 and the N- and C-terminal parts were compared. The matrices (Fig. 2) show that the fast muscle proteins from both chicken and rabbit are rather closely related and have only half the number of differences found between any two of the three rabbit proteins. In the case of the three rabbit proteins the number of differences between any two of them are approximately the same. When the N- and C-terminal halves are compared this general pattern is still maintained but mutations have accumulated in the N-terminal half at approximately twice the rate observed in the C-terminal half. There is some indication that the N-terminal halves of the rabbit slow and cardiac troponin I are more similar than either is to the rabbit fast troponin I and also that the C-terminal halves are correspondingly more different, but it is doubtful if this is significant.

The only other component of the troponin complex for which comparative sequence data are available are troponin C. The sequences of three fast skeletal muscle troponin C components have been published, from rabbit⁸, chicken²⁰ and human muscle²¹ and also the sequence of one cardiac troponin C from beef²². The difference between the rabbit and chicken proteins is 11% while there is only one difference between the rabbit and human proteins. All three fast muscle proteins differ from the cardiac protein by between 30% and 35%. This suggests that troponin C is a somewhat more conservative protein than troponin I.

In a comparison of the sequences the most striking feature is the extra 26 residues which the cardiac protein has at the N-terminal end which are not shared by the proteins from either fast or slow muscle. Apart from the N-terminal region the greatest differences are found in the region of residues 181–184 where one, two and three deletions have to be introduced into the rabbit slow, cardiac and fast muscle sequences respectively to fit them to the chicken fast muscle sequence. There is no discernable pattern in the sequence in this region and this is made more curious by the fact that the sequence on either side of this region is invariant. The sequence of the rabbit slow muscle protein includes a proline at residue 182 and this region may represent a bend in the polypeptide chain where mutations can be tolerated without affecting the overall three-dimensional structure.

Predictions of the secondary structure have been made^{23,24} and give values of about 45% α -helix and 10% β -sheet in rabbit skeletal troponin I whereas values determined from circular dichroic and optical rotary dispersion methods give values of 29% and 20% for α - and β -structure respectively²⁵, which are somewhat at variance with the predictions. There are two regions where concentrations of proline residues are found—in the regions of residues 76 and 137. The predicted structures emphasise that these are likely to be associated with bends in the structure, dividing the molecule into three roughly equal sections. These considerations, together with the highly polar nature of the proteins suggest that they exist as fairly open structures. In each case the charged amino acids account for some 40% of the residues and each protein possesses a net positive charge, this being 8 and 9 respectively in the case of rabbit and chicken fast muscle troponin I and 14 and 18 in the case of rabbit cardiac and slow muscle troponin I. The higher charge on the slow muscle protein is a consequence not only of an increased number of lysine and arginine residues but also of a decrease in the number of

aspartic and glutamic acid residues, there is not however any marked difference in the charge distribution in each molecule.

Studies on the phosphorylation of the rabbit fast and cardiac muscle troponin I show that a number of sites can be phosphorylated using phosphorylase kinase and a cyclic AMP-dependent protein kinase^{26–28}. The position of these sites is shown in Fig. 3.

The major phosphorylation sites in the rabbit fast muscle protein are at residues 37 and 146 (threonine 11 and serine 117 in the fast muscle troponin I sequence¹¹). Phosphorylation at both these positions is blocked in the presence of troponin C and it is doubtful if phosphorylation at these sites is of any physiological significance although they might play a part in the initial assembly of the troponin complex. In each of the proteins there is either a serine or a threonine present at positions 37 and 146 and the sequence around these residues shows considerable homology, it is possible that each of these positions may be phosphorylated in appropriate conditions, but with the exception of serine 146 (ref. 28) in cardiac troponin I this has not yet been demonstrated. The major phosphorylation site in cardiac troponin I is at serine 20^{28,30}, which is in the extra N-terminal part of the sequence. This residue is rapidly phosphorylated by cardiac cyclic AMP-dependent protein kinase and since it has been shown by Solaro *et al.*³⁰ to be phosphorylated when the perfused heart is stimulated with adrenaline, it is tempting to speculate that the part of the sequence which is unique to the cardiac protein is of functional importance in the regulation of cardiac muscle contraction.

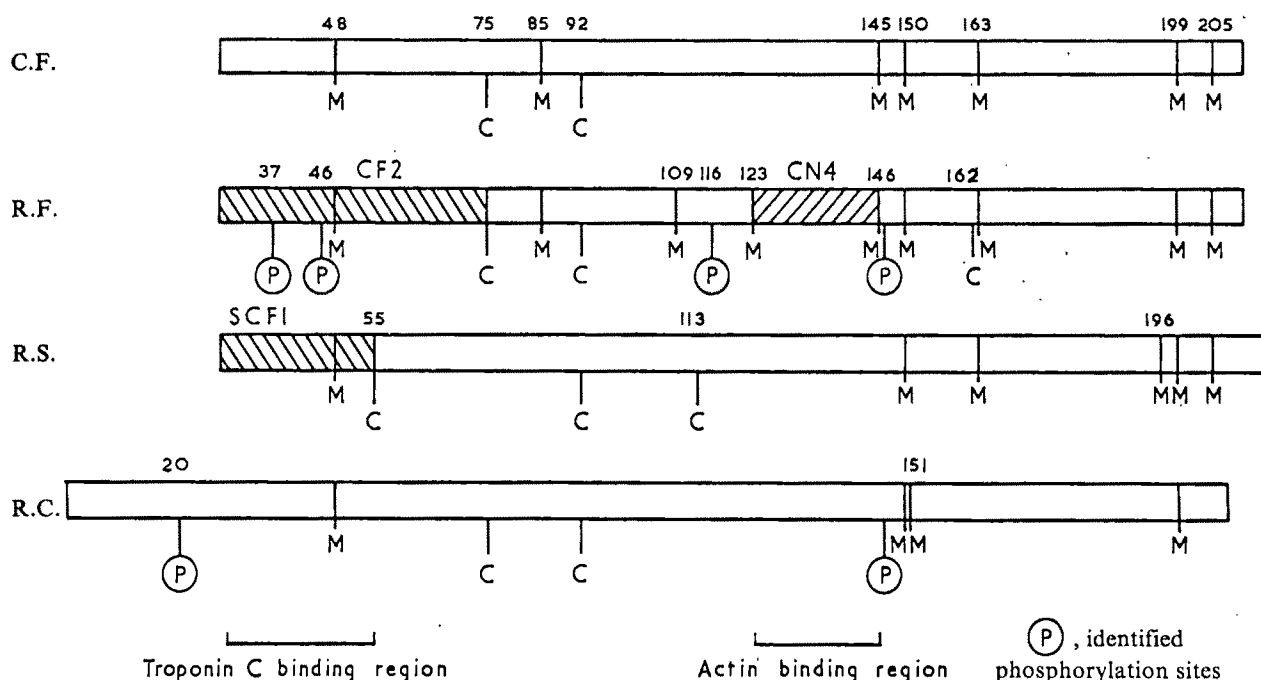

Fig. 3 Schematic representation of troponin I proteins from chicken fast (C.F.), rabbit fast (R.F.), rabbit slow (R.S.) and rabbit cardiac (R.C.) muscle. C, cysteine residues; M, methionine residues. The numbering system is that for the cardiac protein as shown in Fig. 1. In the R.F., R.S. and R.C. proteins only unique identified phosphorylation sites, C and M residues are numbered. The shaded areas indicate the fragments which interact with troponin C (CF2 and SCF1) and actin (CN4) as discussed in the text.

Biological activity of troponin I peptides

Two regions of the rabbit fast muscle troponin I molecule have been implicated in interactions with other components of the thin filament by Syska *et al.*³¹. The cyanogen bromide fragment CN4 (residues 124–145) has been shown to inhibit the actomyosin ATPase, this inhibition being enhanced by tropomyosin and reaching up to 70% of the inhibition obtained with whole troponin I and tropomyosin. This fragment has also been shown by affinity chromatography to bind to actin and also, to some extent, to troponin C. The troponin C binding region has been located at the N terminus of the molecule, partly by the inhibition of threonine-37 phosphorylation²⁹ and more particularly by the demonstration of the binding of the cysteine cleavage fragment CF2 (residues 27–74) to troponin C, both by affinity chromatography and gel electrophoresis³¹.

A consideration of the methionine positions in each of the proteins (Fig. 3), shows that methionine 123 is unique to rabbit fast muscle troponin I. It has probably arisen fairly late in the evolution of fast muscle troponin I and is therefore unlikely to occur in proteins from other sources. It is thus not possible to prepare analogous fragments from the other proteins in order to compare their inhibitory activity. Inspection of the sequence in this region (Fig. 1) shows, however, that it is one of the most strongly conserved in all of the four proteins. With the exception of residue 124, where all the proteins differ, the replacements in general involve strongly conservative hydrophobic residues. There is also a Thr/Pro replacement at position 138 in the cardiac protein and a possible extra leucine at position 141, which has been discussed above. It seems unlikely that any of these changes would affect the inhibitory activity significantly and if there are real differences in this their cause must be sought in other parts of the troponin I structure. This constancy of sequence at the actin binding site is perhaps not surprising in view of the very conservative nature of actin itself.

It is difficult to define the troponin C binding site as precisely as that for actin binding as appropriate fragments are not available. The cyanogen bromide fragment CN5

(residues 27–48) from the rabbit fast muscle protein shows some troponin C binding activity but is not nearly as effective as CF2. It is probable that the binding site spans methionine 48 but may not extend as far as cysteine 75. The rabbit slow muscle protein has an extra cysteine at residue 55 and the fragment produced by cleavage at this residue has been shown to bind to a troponin C–Sepharose column¹⁶, but owing to incomplete cleavage the amount of fragment obtained was small and no quantitative estimate of binding could be obtained. On the basis of homology the most likely binding site is between residues 36 and 52 but even in this region there is considerable variation.

As noted above, the inhibitory peptide (residues 124–145) has some binding affinity for troponin C. Weeks and Perry³² have shown that two of the large cyanogen bromide peptides from troponin C will neutralise the inhibition of the actomyosin ATPase by troponin I and will also inhibit phosphorylation at residues 37 and 146. It is not clear, however, if these observations indicate a second specific binding site for troponin C on the troponin I molecule, in the same position as the actin binding site, or whether they are due to strong ionic interactions between highly acidic peptides and a highly basic region in troponin I.

It is clear from the comparison of the sequences that the genes coding for the three types of striated muscle troponin I diverged at much the same time in evolutionary terms and well before the divergence of birds and mammals.

The overall rate of evolution has been significantly greater than that for troponin C and this must be a reflection of the differing constraints placed on the tertiary structures. Troponin C has four Ca^{2+} binding sites and also interacts with two other components of the thin filament. When one of the Ca^{2+} binding sites is lost, as in the cardiac protein²², the sequence in this region is found to vary considerably. Troponin I has only two protein binding sites and thus a higher rate of mutation is to be expected. But, as shown above, the N- and C-terminal parts of the molecule have changed at rather different rates—the C-terminal half having much the same rate of evolution as troponin C whereas the N-terminal half has changed at nearly twice this rate.

The constancy of the C-terminal parts is explicable in terms of binding to the strongly conserved actin molecule and this would suggest that the mechanism for the inhibition of the actomyosin ATPase is the same for each of the three types of striated muscle troponin I. The much greater variability in the N-terminal part of troponin I and in particular in the troponin C binding region is somewhat surprising in view of the conservative nature of troponin C itself and this may reflect subtleties in the interaction of troponin I with troponin C which may only be appreciated from an understanding of the three-dimensional structure of the troponin complex.

We thank Professor S. V. Perry and Dr A. J. G. Moir for discussions and the MRC for financial support.

letters to nature

Discovery of an X-ray QSO

WE report here the discovery of an X-ray emitting QSO, the first to be initially identified from X-ray observations. Previously, the only QSO known to be an X-ray source was 3C273 (refs 1 and 2). The new QSO has been found within a 40'' error circle established by the SAS-3 X-ray Observatory. The SAS-3 error circle lies within the Ariel V error box (~0.2 square degrees) for the source 2A 2251–179 (ref. 3). Following the convention for optical QSOs, we have designated the optical object MR2251–178. The X-ray luminosity (2–11 keV) of this object, presently $\sim 5 \times 10^{44}$ erg s⁻¹, has been as large as $\sim 1.6 \times 10^{46}$ erg s⁻¹ (in 1975) and exceeds the optical luminosity by a factor of ~10. Among known compact X-ray sources, only 3C273 has a greater luminosity. Also, in radio observations at 4,885 MHz with the NRAO Very Large Array (VLA), we have discovered a point-like radio source coincident with MR2251–178.

A 12° × 12° field near 2A2251–179 was observed with the rotating modulation collimator (RMC) system (ref. 4) on the SAS-3 X-ray Observatory from 11.1 August 1977 to 13.5 August 1977. Data from 36 orbits (effective integration time of 9.7×10^4 s) have been analysed.

Detection of a source within the error box for 2A2251–179 was achieved in each of the two independent RMC detectors. The statistical significance of the detection was 6.2σ in the 2!3 FWHM detector (2–11 keV) and 5.7σ in the 4!5 FWHM detector (2–11 keV). In Table 1 the results of these two independent detections are given, including spectral data for the

two energy channels in each of the two detectors. While the spectral shape cannot be uniquely determined, the data are consistent with a power law having a photon number index of 1.5 ± 0.5 (assuming $E_0 \gtrsim 2$ keV; ref. 5). The flux is $2.5 \pm 0.4 \times 10^{-11}$ erg cm s⁻¹ (2–11 keV). If we combine the two independent position determinations according to the technique described by Doxsey *et al.*⁴ we obtain the following position for the X-ray source (in subsequent catalogues, the X-ray source will be designated 2S2251–178).

$$\alpha(1950) = 22 \text{ h } 51 \text{ min } 25.4 \text{ s}, \quad \delta(1950) = -17^\circ 50' 40'' \\ \text{error circle radius (90\% confidence): } 40''$$

In Fig. 1, we show the Ariel V error box for 2A2251–179 (0.187 square degrees in area; ref. 3) and the refined SAS-3 error circle reported here. Both are superimposed on a Palomar Observatory Sky Survey (POSS) blue plate. Figure 1 inset shows only the SAS-3 error circle, but with a scale factor twenty times larger. Within the SAS-3 error circle, there are only 2 conspicuous objects ($m_v \lesssim 20$) visible on the POSS plates. They are denoted '1' and '2' on the inset. Object 1 possibly is a compact elliptical galaxy, whereas Object 2 is starlike. There is no marked difference between the red and blue POSS images of either object. Coordinates for these two objects were measured on POSS glass plates at Kitt Peak National Observatory (KPNO) by S. Kleinmann. Plates from the Tololo–Michigan Objective Prism Survey (previously taken with the 61 cm Curtis Schmidt telescope at Cerro Tololo; refs 6 and 7) were then examined. On these plates, the spectrum of Object 1 is obscured in part by that of Object 2. In the most remarkable spectrum of Object 2, bright emission lines from the following species are evident: Hβ, [OII] λ3727, [NeIII] 3869, Hγ, and probably [NeV] λ3426 and HeII λ4686. Using 4 lines in the 3,500–5,350-Å interval, we determined a redshift of $z = 0.0680 \pm 0.003$. This implies a distance of 410 Mpc, assuming $H_0 = 50$ km s⁻¹ Mpc⁻¹. Based on the diameter of its POSS image, the apparent magnitude of Object 2 is $B \sim +16$.

Table 1. X-ray observations of MR2251–178 (2A2251–179) by SAS-3

Collimator f.w.h.m.	Energy band (keV)	Counting rate (s ⁻¹)
2!3	2–6	0.45 ± 0.08
	6–11	0.14 ± 0.05
4!5	2–6	0.30 ± 0.06
	6–11	0.13 ± 0.05

Fig. 1 The QSO MR2251-178 and the X-ray source 2A2251-179. 'A' and 'S' denote the Ariel V error box and the SAS-3 error circle, respectively. The inset shows the SAS-3 error circle enlarged by a factor of 20. Object 2 is MR2251-178. Photographs are taken from the Palomar Sky Survey Plates National Geographic Society).

The B luminosity of the object is then $\sim 5 \times 10^{43}$ erg s $^{-1}$, while the X-ray luminosity is $\sim 5 \times 10^{44}$ erg s $^{-1}$ (2-11 keV). The position of the optical object (designated MR2251-178) is

$$\alpha(1950) = 22 \text{ h } 51 \text{ min } 25.89 \pm 0.03 \text{ s}, \\ \delta(1950) = -17^\circ 50' 54''.2 \pm 0''.5$$

The coordinates of the centroid of Object 1 were also measured at KPNO. They are

$$\alpha(1950) = 22 \text{ h } 51 \text{ min } 25.82 \pm 0.03 \text{ s}, \\ \delta(1950) = -17^\circ 50' 15.3'' \pm 0.5''$$

A search for radio emission from MR2251-178 was carried out at a frequency of 4,885 MHz using 6 antennas of the NRAO Very Large Array (VLA) in New Mexico. Operating with 50 MHz bandwidth and system temperatures of roughly 60 K, the six 25-m antennas form an aperture synthesis system capable of easily detecting 1 mJy sources in a 5' field in 1 h. With the six antennas arranged in a linear array, 7.7 km in length, the resolution of the system is < 1 arc s. Aperture synthesis maps of the field containing MR2251-178 made with 1.8 and 2.4 h of data on 4 and 6 October, 1977, independently show the presence of a dominant 3.2 ± 0.3 mJy point source at a position of

$$\alpha(1950) = 22 \text{ h } 51 \text{ min } 25.90 \pm 0.04 \text{ s}, \\ \delta(1950) = -17^\circ 50' 53.5'' \pm 1''$$

No variability was noted between the two dates and the source was < 1 arc s in extent.

In the field containing MR2251-178, there is also an extended radio source of very low surface brightness at

$$\alpha(1950) = 22 \text{ h } 51 \text{ min } 25.8 \pm 0.8 \text{ s}, \\ \delta(1950) = -17^\circ 50' 20'' \pm 10''$$

This source has a size of the order of 30'' and contains at least 10 mJy of radio flux at 4,885 MHz. Because of the elongation of the synthesised beam, it is not possible at the present time to discuss the detailed structure of this extended source; however, considering its position and size, it is very likely associated with Object 1 in Fig. 1.

Based on the positional coincidence (~ 40 arc s), we regard the identification of the X-ray source 2A2251-179 with the optical object MR2251-178 as virtually certain. The association of the VLA radio point source with MR2251-178 is certain (~ 1 arc s positional coincidence). The classification of MR2251-178 as a QSO is based upon its stellar appearance on POSS plates, its redshift, and its high luminosity. It is possible that it could be an extreme Seyfert galaxy. This, however, would require that its luminosity be greater than

that of any known X-ray-emitting Seyfert galaxy (refs 8 and 9). 2A2251-179 is reported to vary by a factor of ~ 10 in the 2A catalogue (ref. 3). At the maximum brightness reported, the 2-11 keV luminosity would be $\sim 1.6 \times 10^{46}$ erg s $^{-1}$. This exceeds the maximum value reported for the Seyfert galaxy of highest reported X-ray luminosity, 3C390.3 (refs 10 and 11).

Among the known compact X-ray sources, only 3C273 has a maximum luminosity greater than MR2251-178 (ref. 10). The ratio of X-ray to optical emission we have observed for MR2251-178 is $\sim 10:1$ compared to a ratio of $\sim 1:1$ in 3C273 and typical X-ray Seyferts (ref. 10). Thus, judging from available data, the energy budget of MR2251-178 is dominated by its X-ray emission. Accurate assessments of its bolometric luminosity must await infrared and high energy (> 10 keV) X-ray measurements.

The redshift of MR2251-178 would place it among the closer QSOs. In all, there are only 5 (out of 633) QSOs in the list of Burbidge, Crown, and Smith (ref. 12) which have smaller redshifts. At the redshift distance of MR2251-178, the projected separation between it and Object 1 is ~ 75 kpc.

The presence of the extended radio source near Object 1 may suggest a possible link to MR2251-178. A redshift measurement of Object 1 would clarify this possibility.

The optical and radio properties of MR2251-178 are such that it is unlikely that it would have been detected in pre-Tololo surveys. In the optical, it would likely have been passed over as an uninteresting field star, while in the radio, it is too faint to have been detected in any standard survey to date. Thus, there could be many such sources. Even if their number density were as great as that of Seyfert galaxies ($\sim 0.5\%$ of all galaxies; ref. 13), they could have been overlooked in optical searches, since the objects would be ~ 2.5 mag fainter for a given X-ray luminosity than are the Type 1 Seyfert galaxies studied by Ariel V (ref. 8), of which the optically faintest was $m_v \sim 14.5$. In view of the hard spectrum of MR2251-178 in the X-ray region (comparable in index to the diffuse X-ray background; ref. 14), the general population of such objects could make a substantial contribution to the X-ray background.

Observation of X-ray eclipses from LMC X-4

THERE are six known X-ray sources in the Magellanic Clouds: five in the Large Cloud and one in the Small Cloud^{1,2}. Until recently, only SMC X-1 was known to be in a binary system³. Chevalier and Ilovaisky⁴ have now shown that the optical emission of the suggested counterpart of LMC X-4 (ref. 5) exhibits ellipsoidal light variations with an inferred binary period of 1.408 d. Previous X-ray observations have indicated that LMC X-4 is highly variable on time scales from minutes to months^{2,6–8}. We report here the detection of several eclipses of LMC X-4, which confirms it as the second known extragalactic X-ray binary. We also discuss briefly the inferred value of the mass of the compact X-ray star.

LMC X-4 was observed on four occasions with the X-ray detectors on SAS-3. The first observation⁶ was made with the Rotation Modulation Collimator system (RMC) during 20.5–26.4 February 1976 (UT). During the interval 15.8–17.6 October 1976 (UT), LMC X-4 was scanned twice per satellite orbit

with the Right Slat detector system^{9,10}. The Y-axis detectors^{9,10} were then pointed continuously at LMC X-4 during the intervals 22.2–23.2 and 23.99–24.32 May 1977 (UT). During the first of these pointed observations, SAS-3 was operated with a special telemetry mode whereby the data from the 6–12 keV channel of the Horizontal Tube system^{9,10} were recorded with a temporal resolution of 8 ms (ref. 11). For the second pointed observation, as well as the scanning and RMC observations, the normal 0.83 s time resolution of the satellite was used.

LMC X-4 was extremely weak compared to the non-X-ray background during most of our observations. We were, therefore, unable to obtain accurate intensities for the source. Instead, we assigned a qualitative description to the observed intensities as

Fig. 1 Orbital X-ray light curve for LMC X-4. The 'digitised' X-ray intensities for LMC X-4, given in Table 1, are folded modulo the trial orbital period 1.40815 d. The apparent eclipse of the X-ray source has a duration of 0.23 ± 0.02 d and is centred at JD 2443068.01 ± 0.02 .

follows: 1 when the intensity was at least 3σ above the background, 0 when it was less than 1σ above the background and 1/2 when we could not determine definitively whether the source was 'on' or not. We then compiled a list of these intensity states, one for each scan during the scanning observation and one for every satellite orbit during the other observations. The results are presented in Table 1.

It is evident from Table 1 that LMC X-4 was 'off' for ≥ 5 h on six separate occasions. This behaviour is similar to the eclipses observed in other eclipsing X-ray binaries^{1,2}. Furthermore, the last two 'off' states occurred very close to the times when the unseen secondary was predicted to be behind the primary⁴. Unfortunately, the orbital period determined from the optical data is not sufficiently accurate to determine whether the earlier X-ray 'off' states occurred at a predicted eclipse time also.

The X-ray 'intensities' from all four observations were folded modulo trial binary orbital periods between 1.404 d and 1.412 d in steps of 0.0001 d. The period range is chosen to be within two standard deviations of the optical period⁴. Figure 1 displays the 'light' curve for the trial orbital period of 1.40815 d. An eclipse is clearly discernible with a width of 0.23 ± 0.02 d. (It is difficult to assign a formal confidence to the errors quoted in this paragraph: however, we regard these errors as conservative limits.) When the data were folded at periods different from 1.40815 d by more than 0.00020 d, the resulting 'eclipses' were significantly shorter and eventually disappeared. We conclude that we have observed an X-ray eclipsing phenomenon with the above binary period, and with an eclipse centre at JD 2443068.01 ± 0.02 . This confirms the proposed optical identification of LMC X-4.

A search for X-ray pulsations in the data taken with 8 ms and 0.83 s time resolution was carried out. No significant peaks in the Fourier power density spectrum were observed. From these studies we place an upper limit to pulsing of $\sim 25\%$ of the steady flux with pulse periods ranging from ~ 16 ms to 400 s. We note that if LMC X-4 had a pulsation fraction and pulse shape similar to that of SMC X-1 (refs 13, 14) it would have been only marginally detectable as a pulsar.

From the velocity amplitude of the He(II) emission lines in the LMC X-4 binary system ($475 \pm 25 \text{ km s}^{-1}$; ref. 4), we estimate a lower limit (2σ) to the mass function:

$$f(M) = \frac{m_{\text{opt}}^3 \sin^3 i}{(m_{\text{opt}} + m_x)^2} = \frac{4\pi^2 (a_x \sin i)^3}{G P_{\text{orb}}^2} \gtrsim 11.2 M_{\odot}$$

where m_{opt} and m_x are the masses of the companion star and X-ray star, respectively, i is the orbital inclination angle, $a_x \sin i$ the projected semi-major axis of the orbit of the X-ray star, and P_{orb} the orbital period. To establish the limit on the mass function we have assumed that the He(II) emission arises from a region between the two stars⁴. We further define the mass ratio of the two stars as $q = m_x/m_{\text{opt}}$.

Figure 2 is a plot of contours of constant m_x in the q/i plane for a mass function $f(M) = 11.2 M_{\odot}$. The upper limit⁴ on the velocity of the optical companion [$\sim 79 \text{ km s}^{-1}$ (2σ)] implies that the mass ratio, q , is smaller than ~ 0.17 . Chevalier and Ilovaisky⁴ argued that i must be greater than $\sim 70^\circ$, because of the large amplitude of the ellipsoidal light variations. The measured X-ray eclipse half-angle, θ_e , is between 27° and 31° . If we assume that the optical companion fills at least 90% of its Roche lobe, then the above limits on q , i , and θ_e restrict m_x to be greater than $\sim 1.1 M_{\odot}$. (For a more complete discussion of this method of mass estimation, see refs 15, 16.) As the value of $f(M)$ we adopted is only a lower limit, we cannot provide a meaningful upper limit to m_x . The shaded region of Fig. 2 shows the allowable range of values of m_x for the various constraints imposed. If $f(M)$ is larger than $11.2 M_{\odot}$, the contours of constant m_x will shift to the lower right of the q/i plane, thereby increasing the lower limit on m_x . We note that if the data point with 'intensity' = $1/2$, which occurs during

Fig. 2 Constraints on the mass, m_x , of the X-ray star in LMC X-4. The light solid curves are contours of constant m_x in the mass ratio/orbital inclination angle (q/i) plane (see text), for a mass function $f(M) = 11.2 M_{\odot}$: a-f are for $m_x = 3, 2.5, 2, 1.5, 1$ and $0.5 M_{\odot}$, respectively. The heavy solid curves are constraints imposed by the assumption of various orbital geometries and eclipse angles; θ_e (see ref. 14): x, y and z represent $(1.0 R_T, \theta_e 27^\circ)$, $(1.0 R_L, \theta_e 29^\circ)$, and $(0.9 R_L, \theta_e 31^\circ)$, respectively, $1.0 R_T$, $1.0 R_L$, and $0.9 R_L$ denotes cases where the optical companion star fills 100% or 90% of its critical tidal or Roche lobe, respectively. The other constraints on q and i are discussed in the text. The hatched region denotes the acceptable range of values of m_x for $f(M) = 11.2 M_{\odot}$. For larger values of $f(M)$ the contours of m_x shift down and to the right in the plot; all other features remain fixed.

the eclipse (Fig. 1), actually represents an 'on' state, the eclipse half-angle would then be reduced to $\sim 20^\circ$. This also has the effect of increasing the lower limit on m_x .

Since the completion of this work, we have become aware of a similar study¹⁷ by the X-ray group at the Mullard Space Science Laboratory. The values reported for the X-ray eclipse ($0.206 \pm 0.008 \text{ d}$) and the orbital period ($1.413 \pm 0.007 \text{ d}$) are in good agreement with the corresponding values quoted in the present work, though of differing precisions.

The authors wish to thank the SAS-3 group for their assistance during this study and, in particular, G. Jernigan and P. Joss for helpful discussions and P. Hertz for preparing the figures. S.R. acknowledges support from the Alfred P. Sloan Foundation. This work was supported in part by NASA.

Discovery of eclipsing nature of LMC X-4

THE Sanduleak-Philip optical candidate for LMC X-4 (ref. 1) has been reported by Chevalier and Ilovaisky² to be part of a 1.4-d binary system. Six days of data taken from an extended Ariel V observation of the LMC are shown in Fig. 1 and X-ray eclipses 5 h long can be clearly discerned every 1.4 d. The predicted optical phase zero times are, within the uncertainties, in good agreement with the observed mid-eclipse times, thus confirming the identification and making this the first X-ray eclipsing binary system to be found in the LMC.

The 3.75° FWHM field of view of the proportional counter spectrometer (PCS) was centred on LMC X-4 but also contained LMC X-1, LMC X-3 (ref. 3) and AO538-66 (refs 4, 5). The three latter sources plus contributions from the particle and X-ray backgrounds are responsible for the residual flux seen during LMC X-4 eclipses. The gaps in the data are caused by the satellite turning off during its night time, regions of high charged particle background and lost data. In spite of this, both eclipse ingress and egress were seen on two occasions and from these an orbital period of $1.413 \pm 0.007 \text{ d}$ was obtained (phase zero occurring on JD 2443342.614), in good agreement with the optical value of $1.408 \pm 0.002 \text{ d}$ ². Combining the X-ray and optical epochs (obtained 4 months apart) gives an improved period of $1.40838 \pm 0.00027 \text{ d}$.

Figure 2 shows one of the eclipses plotted with a time resolution of 64 s. Entry and exit occur on a timescale of minutes with an eclipse duration on the two occasions where it could be measured of $0.208 \pm 0.008 \text{ d}$ ($\theta_e = 26.2 \pm 1.1^\circ$). This may be combined with the available optical data to derive a mass for the secondary, but this is dependent both on the inclination of the system and the

Fig. 1 The flux seen by the PCS integrated in 8 min time bins. The decline in flux during the last few hours can be attributed to the pointing position moving away from LMC X-4, LMC X-1 and LMC X-3.

assumed radius of the primary star. At present, these two parameters are not sufficiently constrained to improve significantly the estimate of $1-3 M_{\odot}$ already derived by Chevalier and Ilovaisky².

The X-ray data were unsuccessfully searched for evidence of periodicities between ~ 1 s and 40 min with an upper limit of

Fig. 2 One eclipse from LMC X-4 plotted with the finest time resolution available (64 s).

$\sim 20\%$ the mean flux. The overall peak luminosity of LMC X-4 was $\sim 3.4 \times 10^{-10} \text{ erg cm}^{-2} \text{ s}^{-1}$ in the 1.7 to 17.0 keV band which represents a total source output of $1 \times 10^{38} \text{ erg s}^{-1}$. X-ray eclipses were only seen between 15 and 23 July, although the observations lasted from 29 June to 23 July and from 3 to 7 August. Six days of data obtained from 30 June onwards were folded modulo the orbital period and a two sigma upper limit to any residual flux above background (as defined during the predicted eclipse) of $1.8 \times 10^{-11} \text{ erg cm}^{-2} \text{ s}^{-1}$ was found. This represents an upper limit to the source luminosity of $5 \times 10^{36} \text{ erg s}^{-1}$.

Four flares each lasting between 10 and 20 min were seen and they are shown in Fig. 3 plotted with the shortest time resolution available of 64 s. These 'outbursts' could have originated from any source in the field of view of the PCS. The PCS, however, is coaligned with a rotation modulation collimator which can obtain a source intensity averaged over one satellite orbit (typically ~ 50 min out of every 100) and combining two of the orbits when the flares occurred indicated a factor two increase in the intensity from LMC X-4 (G. Carpenter, personal communication). This suggests that the outbursts did originate from LMC X-4 and that the peak represents a source luminosity of $9 \times 10^{38} \text{ erg s}^{-1}$. We note that Epstein *et al.*⁶ have reported 20-s

Fig. 3 Four outbursts plotted with 64 s time resolution. The times (a, b, c, d) at which they occurred are indicated in Fig. 1. The 1σ uncertainties are the square root of the count rate.

events of comparable luminosity from the vicinity of LMC X-4 and these may be related to the four outbursts reported here.

I thank G. F. Carpenter of Birmingham University and P. J. N. Davison for useful discussions.

A search for rapid optical periodicities from Cyg X-1

ACCORDING to the most widely accepted model of the X-ray source Cyg X-1, the X rays are produced in a gas disk surrounding and accreting into a black hole with a mass of about $10M_{\odot}$. The accretion disk is maintained by matter transferred from the binary companion of Cyg X-1, the blue supergiant HDE226868. The X-ray luminosity of Cyg X-1 is known to vary randomly on a wide range of time scales, from many days to a few milliseconds, with the shortest of these time scales corresponding to the dynamical time scale of the innermost stable orbit around the black hole^{1,2}. The optical luminosity of the Cyg X-1 system is also known to vary on time scales of days³, but only one case of extremely rapid optical variability has been reported^{4,5}. The properties of the rapid variations were most unusual. The variations were transient and were detected only four times, but they occurred sufficiently frequently that three of these detections occurred during the total of only 2 h of observations accumulated by Auriemma *et al.* in July 1975^{4,5}. The variations were nearly periodic, with periods of 83.53 ms, 83.71 ms, 83.59 ms, and with $|\Delta P/P| \sim 2 \times 10^{-4}$. The periodicities were long-lived, lasting at least 6 min and probably over 10 min, so that the pulse trains consisted of over 4,000 pulses. The amplitudes of the pulses were large, up to 0.042 mag. No comparable behaviour has been detected in the X-ray light curve of Cyg X-1, and it is far from clear that this behaviour is consistent with our present conceptions of accretion disks. Thus, the detections of these pulses, if confirmed, would be of some importance since they would require a revision of the models for Cyg X-1. Therefore, we have taken an extensive set of observations of Cyg X-1 with the purpose of detecting additional examples of the rapid periodicities.

The data were acquired using one or other of the high-speed photometers mounted on the 0.76 m, 0.92 m, or 2.08 m telescopes at McDonald Observatory. Our observational technique consisted of acquiring individual 10-min long light curves of HDE-226868. The light curves were taken through a wide variety of filters, most notably the Johnson U, B, and V filters, the Strömgen v filter, and a 30 Å filter centered on the $\lambda 4,686$ Å line of He II. Each of the light curves was tested for the presence of periodicities at the time it was observed. Our technique for testing for periodicities has already been described in detail⁶. Briefly, for a sinusoidal signal, the test is equivalent to calculating the power spectrum of the light curve, but because of limitations on computer memory and speed, the spectrum is calculated only for a restricted range of frequencies. For Cyg X-1, we chose a frequency range of 11.718 to 12.216 Hz. This frequency range is centred on, and is a factor of nearly 20 greater than the range of the frequencies detected by Auriemma *et al.* We accumulated over 90 h of light curves spaced over 65 nights in September to November 1976 and in May to October 1977. With the exception of a few observations heavily contaminated by clouds, the maximum amplitude of any possible periodic signal during this

time was 0.0029 mag, which is more than a factor of 10 less than the amplitude of the variations detected by Auriemma *et al.* With no exceptions, the power at all frequencies in the tested range was always consistent with white noise.

There are several ways to account for the difference between our results and those of Auriemma *et al.* Cyg X-1 could have changed its properties between 1975 and 1976 so that the periodicities are no longer present or occur far less often. The variations could have been present during our observations, but with periods outside the range of periods we tested. It is also possible that the periodicities detected by Auriemma *et al.* were spurious and of instrumental origin.

Quasi-periodic fluctuations in electron content during a partial solar eclipse

CHIMONAS and Hines^{1,2} have suggested that a solar eclipse might generate gravity waves in the atmosphere. During solar eclipse the localised cooling of the atmosphere in the lunar shadow causes an energy imbalance and the shadow moving at supersonic speed across the Earth's surface could be a continuous source of gravity waves propagating to great distances in the atmosphere. These quasi-periodic wave perturbations in the ionospheric electron density, caused by the coupling between the ionised and the neutral particles, have been detected by various investigators³⁻⁵ at middle and high latitude stations away from the path of the eclipse shadow. Hajkowicz⁶ has reported the observation of perturbations of quasi-periods of less than 2 min, after the October 1976 eclipse. We report here the observation of quasi-periodic fluctuations in Faraday rotation angle Ω and the 1 MHz modulation phase delay ϕ of 40 MHz transmissions from ATS-6 geosynchronous satellite recorded at Trivandrum (dip $0^{\circ}57'S$, geographical longitude $76^{\circ}57'E$) during the partial solar eclipse on 29 April 1976. ϕ directly gives columnar electron density integrated along the radio ray path from the satellite to the receiver; whereas Ω gives columnar integrated electron density only up to an altitude of 2,000 km because of the weightage by the component of the geomagnetic field along the ray path. For ATS-6 to Trivandrum ray path geometry, a change of 10° in Ω will be produced by a change of 0.47×10^{18} el. m^{-2} of electron (el.) content. In contrast to this, 10° change in ϕ will be produced by a change of 0.34×10^{18} el. m^{-2} . The accuracy of measurement of both Ω and ϕ is better than 1° .

On 29 April 1976 the solar eclipse, as seen from the 300 km altitude point on the ATS-6 to Trivandrum ray path, began at 1718h (all times are IST); maximum obscuration of about 20% of the solar disk was at 1802 h; the end of the eclipse was at 1843 h and the sunset time was 2003 h. The values of Ω and ϕ recorded on 29 April 1976 between 1420 h and 1830 h were scaled at intervals of 2 min. The differences between the data and the 10-min moving averages which contain all fluctuations with quasi-periods less than 50 min are plotted against time in Fig. 1; separately for

Fig. 1 Fluctuations of Ω (a) and ϕ (b) on 29 April 1976.

Ω (Fig. 1a) and ϕ (Fig. 1b). Figure 1 clearly shows fluctuations in both ϕ and Ω during the solar eclipse with quasi-periods around 11 min. A striking feature is the relatively quiet period of no fluctuations before and after the eclipse. The maximum amplitude of the total electron content fluctuations is estimated to be about 0.5×10^{16} el. m $^{-2}$ and this is about 1.0% of the total electron content. Similar analysis of the data between 1430 h and 2000 h on 28 and 30 April 1976 did not show any conspicuous quasi-periodic fluctuations. This strongly supports the view that the fluctuations shown in Fig. 1 during the solar eclipse period are in fact due to the solar eclipse.

From Fig. 1, it can be seen that there is not an exact one to one correspondence between the fluctuations of Ω and ϕ although, the ray paths along which they give the integrated electron content are the same. Also ϕ shows relatively clearer periodic fluctuations than Ω . This may be because Ω is weighted by the geomagnetic field.

To study the spectral components, the fluctuations of Ω and ϕ in Fig. 1, during the 128-min interval between 1652 h and 1900 h were subjected to power spectrum analysis with Hamming filter⁷. The power spectrum obtained has a frequency resolution of 0.13 mHz, the Nyquist frequency being 4.166 mHz. In Fig. 2 the continuous and the dashed curves are the power spectra of ϕ and Ω

Fig. 2 Power spectra of the fluctuations in Ω (dashed line) and ϕ (solid line) during the eclipse on 29 April 1976.

respectively. To test the stability of the spectral power estimates, the equivalent number of degrees of freedom of a χ^2 distribution⁷ have been computed and was found to be close to 22 for both the spectra. The 80% confidence limits of the relative spectral power estimate of 0.5 is shown in Fig. 2. The periods (in minutes) corresponding to the prominent spectral peaks in Fig. 2 are:

ϕ	—	12.8	9.8	8.0	6.1
Ω	42.7	16.0	10.7	8.5	6.5

It can be seen from atmospheric gravity wave theory⁸ that the above periods agree with the periods of gravity wave propagating modes at F-region levels. Considering the corresponding peaks in Ω and ϕ shown above it is immediately obvious that the periods are larger in Ω than in ϕ . This difference may be due to the influence of geomagnetic field on Ω .

The effect of the weightage of the geomagnetic field on Ω depends on the period and the vertical wavelength of the propagating gravity wave. For example, the electron density fluctuations at 350 km altitude produce about 50% smaller fluctuations amplitudes in Ω compared with the same electron density fluctuations at 200 km altitude. In Fig. 1, the amplitude of the fluctuations in ϕ is almost the same during the eclipse, whereas in Ω the fluctuations decreased to about 50% during the later part of the eclipse. This indicates that the fluctuations in electron density during the eclipse are not at the same height and that the fluctuations during the later part of the eclipse are at a higher altitude than soon after the eclipse beginning. A steady increase in the effective height of the electron density fluctuations in conjunction with the steady decrease in the geomagnetic field with height, leads to a larger period of the wave as seen on Ω than on ϕ . This upward energy propagation is in fact an important characteristic of the gravity waves.

In Fig. 2, the relatively larger spectral power at larger periods in Ω than in ϕ indicates that the larger period waves are propagating at lower altitudes, where for a given density change the change in Ω is larger because of the large value of the weighting geomagnetic field. This is also borne out by gravity wave theory⁸ that large period waves propagate at low elevation angles.

It can be seen that electron content fluctuations are shown better in ϕ than in Ω . The non-observation of clear fluctuations in electron content during earlier solar eclipses³⁻⁵ may be because all these measurements were of Ω fluctuations.

It is difficult to calculate the amplitude of the gravity wave produced by solar eclipse in the neutral particles and the consequent fluctuations in electron density by collisional coupling between the neutral and ionised particles. It is known⁸, however, that the gravity wave amplitude increases exponentially with height whereas the ion neutral collisional frequency decreases exponentially in the same way. This may perhaps lead to the constant amplitude of the fluctuation of ϕ in Fig. 1.

A simple calculation of ozone depletion by chlorofluoromethanes using a two-dimensional model

THE possible perturbation of the total amount of ozone in the atmosphere due to man's activities has been the subject of much recent research. The vast majority of perturbation calculations have been performed using one-dimensional models in which variations in the vertical alone are considered. I describe here some simple calculations of the effects of chlorofluoromethanes on the ozone layer using a two-dimensional (latitude and height), time-dependent numerical model in which the mean circulation is computed at each time step. In our two-dimensional treatment the eddy transports of heat and matter are calculated using two-dimensional eddy diffusion coefficients, based on atmospheric statistics, and the eddy momentum fluxes are average monthly values for 1973 deduced from the Nimbus V Selective Chopper Radiometer measurements. The approach has proved successful in modelling many features of the unperturbed atmosphere and, in particular, of the behaviour of ozone in the stratosphere¹.

In the model the photochemical source of ozone is linearised such that

$$\frac{\partial [O_3]}{\partial t} = \frac{[O_3]_e - [O_3]}{\tau}$$

where $[]$ represents a mass mixing ratio, $[O_3]_e$ is the ozone equilibrium mixing ratio and τ the time constant. $[O_3]_e$ and τ are specified as functions of latitude, height and season, the values being appropriate to a photochemical scheme including the oxides of nitrogen and hydrogen. The solar heating is dependent on the modelled ozone concentrations, thus coupling the chemistry, radiation and dynamics. Further details of the model are given in refs 1 and 2.

A complete calculation of the effect of chlorofluorocarbons on ozone would require simulation over many years. The purpose of this letter is not to predict the magnitude of these effects, however,

Fig. 1. The latitude-time section of the percentage change in total ozone between experiments E1 and E2 for one model year. Model days 730–1095.

Fig. 2. The latitude-time section of the percentage change in total ozone between experiments E1 and E3 for one model year. Model days 730–1095.

but rather to indicate that there are important latitudinal and seasonal variations which need to be considered. For this reason it seems justifiable to make some rather gross approximations. The starting point for the study is the work of Crutzen³. Using a one-dimensional, steady-state model, he calculated the reduction in ozone due to continued release of chlorofluoromethanes at a rate appropriate to the mid-1970s. Large changes are predicted for the upper stratosphere where ozone is expected to be close to photochemical equilibrium.

The results of three different calculations will be described here: E1, an unperturbed run very similar to that described in Harwood and Pyle¹; E2, a perturbed run in which the equilibrium values are modified, in a manner based on Crutzen's work as described below, and which uses exactly the same temperature and wind fields as in E1; E3, an experiment in which the equilibrium values are again modified but in which the perturbed ozone concentrations are used in the calculation of solar heating. Thus, the feedback between the ozone amount, temperature and the mean circulation is included in E3.

In all three runs the ozone equilibrium concentrations are taken to be temperature dependent according to the expression $[O_3]_e(T) = A \exp(1,000/T)$ (see Barnett *et al.*⁴). The results of E1, including this temperature dependence, are similar to those described by Harwood and Pyle¹.

In the perturbed runs the equilibrium values were modified in the following manner. The stratospheric values of $[O_3]_e$ were modified by the percentage calculated by Crutzen³ (table 1 ref. 3). τ , too, depends on $[O_3]_e$ as well as on the concentration of chlorine compounds and the dissociation rate of ozone. Allowance was made for all these factors in E2 and E3.

Figure 1 shows the latitude-time section of the percentage difference in total ozone between E1 and E2. The magnitudes clearly depend on the initial assumptions and should not be emphasised. What is of interest is the large variation with latitude and time. The largest reductions occur in high latitudes where the total ozone itself is largest and at these latitudes the reductions vary by a factor of two with the time of year. In equatorial regions, where total ozone is lowest, there is even an increase in the total ozone throughout part of the year. This is due to the 'self healing' effect whereby increased penetration of solar radiation in the lower stratosphere increases ozone there. Ozone is produced in the equatorial lower stratosphere and transported in the upward branch of the Hadley cell to regions where it has been depleted.

The increased upward transport in E2 can, at certain times of the year, cancel the reductions at higher levels.

The above result is due to a combination of dynamical and photochemical processes. If a climatological ozone distribution were reduced by the same factors as $[O_3]_e$, the largest percentage reduction in total ozone would be found in equatorial latitudes. On the other hand, the percentage reduction of the equilibrium values between E1 and E2 does have largest depletion in high latitudes but in this case the magnitudes differ considerably from those in Fig. 1.

In E3 the reduced ozone concentrations are used in the solar heating calculations in the model. One might expect that reduced ozone in the upper stratosphere would lead to reduced solar heating and lower temperatures there. The ozone, though, is temperature dependent; lower temperatures cause the ozone amounts to increase. Hence, the mean circulation, driven in part by the solar heating, differs from that in E1 (and E2, where this feedback was deliberately suppressed). Figure 2 presents the latitude-time section of the percentage difference in total ozone between E1 and E3 and has many similarities with Fig. 1. Surprisingly, the reduction of ozone in E3 is larger than in E2. The stratospheric temperatures in E3 are reduced by a few per cent and the ozone reduction at this level is correspondingly less than in E2. In the mid and lower stratosphere in E3, however, there is an increase in temperature and a decrease in ozone when compared with E2 and this more than cancels the upper stratospheric increase. Thus, for instance, in E3 there is no longer a small increase in total ozone at the equator. That the temperatures in the lower stratosphere are higher in E3 is probably due not only to increased solar heating but also to transport processes. It is evident from E3 that the calculation of ozone reduction is made a more complicated exercise by these important feedbacks between photochemistry, radiation and dynamics.

The results presented here demonstrate the importance of multidimensional models in studies of projected perturbations in atmospheric ozone. An extremely simple photochemical scheme has been used here and there are strong reservations about the absolute magnitude and phase of the calculated reductions in ozone. But, both E2 and E3 demonstrate, unequivocally, important variations in ozone depletion with both latitude and time (and this is confirmed by preliminary results with a model including a much more complete photochemical scheme, data not shown). Furthermore, E3 indicates the importance of including all the important feedback mechanisms.

Quasi-crystals from irradiated photochromic dyes in an applied electric field

In many photochromic systems, and certainly in the spiropyran, the colourless (A) form is much less polar than the photocoloured (B) form¹. Our previous experiments^{2,3} revealed unusual properties of spiropyran in non-polar solvents at low temperatures (173–240 K). On irradiation of these solutions with suitable light there were formed dimers (AB) and charge transfer complexes (CTC $\equiv A_n^+B^-$ with $n \approx 2-3$), and these in turn formed aggregates with degrees of association $>10^8$. The CTC exhibit spectral red shift of about 100 nm as compared to the dimers. The

relative populations of dimers and charge transfer complexes in the aggregates depended both on light intensity and temperature, because CTC formation involves an activation energy of about 5 Kcal mol⁻¹ associated with the interaction of dimers with further A molecules. At temperatures sufficiently low or at light intensities sufficiently high it was possible to obtain aggregates composed of dimers only. When the constant field was applied during irradiation, threads were formed which extended from one electrode to the other (along the electric lines of force). These threads are composed of dimers and CTC, and their absorption spectrum is identical to that of aggregates in solution. Linear dichroism measurements showed that the CTC are oriented along the thread axis, but the dimers are unoriented. These threads were formed only in the

Fig. 1 The absorption spectra of 6-nitro BIPS (concentration in methylcyclohexane solution 5.10^{-4} M), irradiated by ultraviolet light with intensity of 2.10^{-8} einstein cm^{-2} s. *a*, Quasi-crystals, room temperatures, $F = 15 \text{ kv cm}^{-1}$; *b*, aggregates -120°C . *c*, Difference spectrum (absorption of the CTC).

temperature range in which CTC arise in solution. Here we describe investigations of the structure of such threads, which led us to conclude that the threads consist of highly dipolar crystallites composed of the charge transfer complexes and coated by an amorphous phase composed of dimers. These crystallites in the amorphous envelope are oriented along the electric field and joined together to give the quasi-crystalline threads.

Solutions of 6-nitro-1',3',3'-trimethylspiro[2H-1-benzopyran-2,2'-indoline, '6-nitro BIPS' ($R_1 = \text{CH}_3$; $R_2 = \text{H}$) (ref. 4), in methylcyclohexane were studied. An Osram HBO 200 W high pressure mercury lamp in a thin housing was used for irradiation, with Corning glass filter No. 5840 which transmits essentially from 300 to 400 nm. The absorption spectra were measured using a Cary 14 spectrophotometer, and the linear polarised spectra using the same instrument with the attachment described by Jaffe *et al.*⁵. This attachment permits simultaneous measurement of absorptions in two mutually perpendicular directions. This proved useful in the present experiments because the

Table 1 Degree of linear dichroism of the threads from 6-nitro BIPS in methylcyclohexane

Concentration of solution M $\times 10^3$	Applied field kV cm ⁻¹	P_{310} (± 0.03)	P_{010} (± 0.02)

0.4	25	-0.01	0.12

$P_\lambda = (D_{||} - D_\perp)/(D_{||} + D_\perp)$; $D_{||}$ and D_\perp are the optical densities of the threads when the monitoring light is polarised, respectively parallel and perpendicular to the axes of the threads.

threads are rather unstable. But the method limited us to measurements of absorption in specific directions only, that is parallel and perpendicular to the threads axis.

We used spiropyran solutions of higher concentrations ($>10^{-4}$ M) and higher light intensities ($>10^{-8}$ einstein cm⁻² s⁻¹) than in the earlier studies^{2,3}. This permits the production of much higher stationary concentrations of form B and the growth of the quasi-crystals even at room temperature.

Figure 1 shows the spectrum of quasi-crystals obtained from 6-nitro-BIPS at room temperature in an electric field. This spectrum is identical to that of aggregates obtained under the same conditions in the absence of a field. Also the spectrum of aggregates obtained at 153 K in solution is shown, which consist of dimers only without CTC. The difference spectrum, constructed as described previously³, is the absorption due to CTC; this is shown in Fig. 1c. This absorption is red-shifted by about 100 nm with respect to the absorption of the dimers.

The linear dichroism, P_λ (see Table 1) was measured for various initial concentrations of the solution and for various strengths of the applied field. The results show that P_{310} , determined near the maximum dimer absorption, is close to zero; on the other hand, P_{010} , determined near the maximum CTC absorption, is equal to about 0.1, and does not vary with the concentration of the photochrome or the field strength (5–25 kV cm⁻¹).

We shall show that the threads consist of small crystallites of CTC embedded in dimers. The dichroism results then show that there is a random arrangement of the dimers in the threads; on the other hand, the microcrystals in the thread are all aligned, and in such a way that the absorption by the CTC of the light polarised parallel to the thread axis exceeds, although slightly, the absorption of the light polarised perpendicular to this axis. This orientation of the microcrystals must be due to the interaction $F\mu$ between the field of strength F and some permanent dipole moment μ , with $F\mu > kT$. This inequality is satisfied at 293 K and for $F = 5$ kV cm⁻¹ when $\mu > 2.5 \times 10^{-30}$ D. This corresponds to a dipole length $>10^{-5}$ cm which considerably exceeds the size of the complexes $A_n^+B^-$ ($n = 2-3$). The conclusion is that it is associates or microcrystals of CTC rather than the individual CTC which are oriented by the applied field.

We recall that the photocoloured B form of the spiropyrans are merocyanines which readily aggregate in solution to give stacks with a tilted 'deck-of-cards' structure⁶. The absorption of such aggregates are red-shifted by about 100 nm as compared to the absorptions of the corresponding unaggregated molecules. In our case, the stacks as well as the crystals which are formed from the highly dipolar CTC may or may not be dipolar depending on their structures. Our evidence points to the crystals being oriented by the field. Thus we conclude that the crystals are dipolar. Since our measurements of polarised absorption were limited to directions parallel and perpendicular to the thread axis, we

cannot tell whether the observed value of P_{010} is its maximum value, and cannot ascertain the relationship between the orientations of the CTC chromophore and the crystal dipole moment.

Additional structural information has been obtained by X-ray and electron diffraction studies. The X-ray powder patterns of precipitates formed at room temperature in the absence of an applied field and of the quasi-crystalline threads are practically identical; they consist of sharp reflections, the most intense ones corresponding to interplanar spacings of 3.4, 5.0, and 7.4 Å. These sharp reflections are superimposed on a diffuse pattern, the intensity of which rises with increasing dimer content. Thus precipitates formed at low temperature (150 K), which are composed of dimers only, with no CTC, give only the diffuse pattern. Therefore both the precipitates and the quasi-crystals are composed of various proportions of dimers, in a more-or-less amorphous state, and of crystalline CTC.

Electron microscope studies of precipitates formed in the absence of a field show them to consist of globules, $\sim 0.2-0.4$ μ m in thickness. For the electron microscope studies of the threads the latter were produced directly on a parlodion film, carefully dried, and transferred to grids. In the micrograph (Fig. 2) one can see similar globules of those of the precipitates, joined together by straight, narrow portions of the threads, which also prove to be amorphous. Because of the thickness of the globules it is not possible to get distinct electron diffraction patterns from their central parts, but such patterns can be obtained sometimes by focussing on the edges. The patterns thus obtained consist of the reflections from one or more single crystals. The diffraction from the crystals can be readily detected in those cases in which the amorphous envelopes of the globules have been (accidentally) removed. We conclude that crystals are contained in the globules, and that their dimensions are of the same order of magnitude as estimated from spectroscopic data. Further, since limiting dichroism is achieved even at the low field-strength of 5 kV cm⁻¹, the microcrystals seem to be aligned parallel in the threads.

During irradiation of spiropyrans, in non-polar solvents

Fig. 2 Electron micrograph of the quasi-crystals. Scalebar, 1 μ m.

Fig. 3 Scheme of structures of quasi-crystals (a) and aggregates (b).

dimer and charge-transfer complexes are formed. These give solids consisting of amorphous zones of dimer and dipolar crystals of the complexes. In an electric field the crystals coated with dimer are joined together to give quasi-crystalline threads in which the crystals are oriented with their dipolar axes along the lines of force and thread axes. These threads thus form a new, linearly organised form of organic material (Fig. 3).

We thank Professors M. D. Cohen and E. Fischer, and Dr E. Wachtel, for valuable discussions, and Mr M. Kaganowich for the spiropyran.

Rare gas isotopic compositions in diamonds

RARE gas isotopic compositions such as $^{40}\text{Ar}/^{36}\text{Ar}$, $^3\text{He}/^4\text{He}$ and $^{129}\text{Xe}/^{132}\text{Xe}$ in the Earth have provided a powerful tool for understanding the origin and evolution of the terrestrial atmosphere¹⁻⁴. The isotopic information may be obtained from rare gases trapped in some mantle-derived materials such as volcanic rocks, volcanic xenoliths or volcanic gases. Among these mantle-derived materials, diamond seems to be unique due to its almost complete inertness to any known chemical and to its enormous stability against high temperature. Although the presence of O_2 , H_2 , CH_4 , H_2O , CO , N_2 , Ar and CO_2 in diamonds has been

reported^{5,6}. No previous measurement has been made either on elemental compositions or on isotopic ratios of rare gases in diamonds. Here we report on rare gas elemental composition and isotopic ratios in diamond. We found that $^3\text{He}/^4\text{He}$ ratio is more than an order of magnitude larger than the atmospheric value and also $^{40}\text{Ar}/^{36}\text{Ar}$ ratio is significantly higher.

Industrial diamonds we studied are believed to have come from Kimberley Mines, South Africa. The size of the diamonds ranges from about 1 mm to about 5 mm. Some contain black inclusions, some of which are ferromagnetic and appears to be pyrrhotite under a microscope. Existence of pyrrhotite inclusions in diamond is not unusual⁷ and the black inclusions seem to be syngenetic with diamonds. Diamonds are crushed to a few meshes in a stainless steel mortar. Step-heating was made on two batches of samples at 800 °C, 2,000 °C and 2,100 °C in a high vacuum tantalum furnace⁸. Only visible difference between the two batches is that batch 1 is richer in black inclusions than batch 2.

Rare gas elemental abundance and their isotopic ratios are shown in Table 1. Batch 1 gave almost three times more rare gases as batch 2. Also isotopic ratios, $^{40}\text{Ar}/^{36}\text{Ar}$ and $^3\text{He}/^4\text{He}$, of the two batches are quite different. We believe that this is due mainly to difference in the amount of the black inclusions, that is, rare gases in batch 1 may come mostly from the black inclusions, while those in batch 2 are more representative of diamonds. In both cases major degassing is observed at 2,000 °C. A third batch of sample which were heated at 1,500 °C gave off $^{40}\text{Ar} \sim 1 \times 10^{-8} \text{ cm}^3 \text{ g}^{-1}$ at STP which is less than 10% of the rare gases evolved from batch 1 and 2 at 2,000 °C. X-ray analyses on heated samples showed that heating at 1,500 °C for 1 h (batch 3) did not result in graphitisation, but heating at 2,000 °C for 1 h (batch 1 and batch 2) completely converted diamonds to graphite. We conclude, therefore, that graphitisation which accompanies any density change of more than 30% must be responsible for the major degassing of diamonds.

All other rare gases except He, show a similar thermal release pattern. In the case of He, more than 99% was degassed at 2,000 °C suggesting that most of He resided at low temperature sites had been degassed before the experiment, perhaps under high temperature mantle condition. From the similar thermal release pattern of rare gases between batch 1 and batch 2, we conclude that rare gases in the black inclusions occupy similar sites as those in batch 2, the latter being more likely to represent diamond rare gases. This suggests a syngenetic origin of the black inclusions with diamonds.

The K content of evaporates which were deposited on the inner wall of a high vacuum extraction furnace during the graphitisation were measured. The deposits were washed by dilute HNO_3 and the K content in the washed solution was measured with an isotope dilution method. The amount of potassium was 8.22 p.p.m. and 1.97 p.p.m. for batch 1 and batch 2 respectively. Radiogenic ^{40}Ar , which would have been produced in batch 1 diamonds by this amount of K, will exceed the total amount of ^{40}Ar if the age of the diamonds is older than 2,800 Myr. Hence, the diamonds can not be older than 2,800 Myr. If this maximum age is assumed, this will give minimum $^{40}\text{Ar}/^{36}\text{Ar}$ ratio of 670 for the trapped Ar in the batch 2 diamonds. The observed $^3\text{He}/^4\text{He}$ ratio is also minimum, as the diamonds must contain some U as well as K. Therefore, the $^3\text{He}/^4\text{He}$ and $^{40}\text{Ar}/^{36}\text{Ar}$ in the diamonds must be larger than 1.95×10^{-5} and 670. The $^3\text{He}/^4\text{He}$ ratio is significantly higher than those observed in ridge submarine glasses⁹ which are generally regarded to be derived from oceanic upper mantle. The high $^3\text{He}/^4\text{He}$ ratio suggests that the diamonds may be derived from a region different from source regions for oceanic ridge basalts, most likely from deeper region in the mantle. In this connection it is interesting that similar high $^3\text{He}/^4\text{He}$ (2.09×10^{-5}) are observed in Hawaiian volcanic gases⁹, which may be derived from deeper mantle through a hot spot.

Although the origin of diamonds is not fully understood, it is generally assumed that they crystallise from CO_2 saturated fluid phase in the mantle, probably deeper than 100 km or even more. The syngenetic black inclusions occluded in diamonds seem to have been derived from mantle region in which diamonds crystallised. Our results lead us to an interesting speculation that

Table 1 Elemental and isotopic compositions of rare gases in diamond

Sample	Batch 1			Blank 1		Batch 2			Blank 2
Weight (g)		1.98				2.61

¹³⁶ Xe/ ¹³² Xe		0.328 ± 0.012				0.318 ± 0.018			

Other isotopic ratios are indistinguishable from atmospheric values

rare gases observed in batch 2 may be representative of those carried by CO₂ phase, whereas rare gases in batch 1, or more specifically rare gases in the black inclusions, is rather indicative of a region where the diamonds occluded the former.

Ar isotopic ratios observed in diamonds do not seem to support the speculation¹⁰ that diamonds were formed from materials in subducting ocean sediments, since even very small amount of seawater contamination (say less than 0.1%) which would necessarily accompany ocean sediments would reduce ⁴⁰Ar/³⁶Ar isotopic ratio to almost atmospheric value (295.5) because of relatively very high Ar content (about 0.03%) in seawater. The observed ⁴⁰Ar/³⁶Ar is much higher than the atmospheric ratio, ruling out any noticeable amount of seawater contamination.

On melting icebergs

THE feasibility of towing icebergs to their coasts and melting them on arrival to provide a supply of fresh water is being studied in various parts of the world. Saudi Arabia, Australia and California¹ are amongst those considering such a project. One suggestion for melting the icebergs is to run each iceberg aground in water approximately 250 m deep, the mean depth of Antarctic icebergs. A relatively shallow pen would then be built around the iceberg and it is conjectured that the melt water will rise, without much mixing, into the pen, from where it will be siphoned off for subsequent use. Neshyba² claims, however, that melt water produced by icebergs may be responsible for a large amount of upwelling and mixing in the Antarctic's Weddell Sea. He asserts that as the melt water rises up the side of an iceberg, it entrains a sizeable quantity of warmer, saltier water from

Fig. 1 Temperature (T) and salinity (S) profiles measured in the upper 400 m of the Weddell Sea (adapted from Fig. 3 of Foster and Carmack³). a, Near the Scotia Ridge at the northern edge of the Sea; b, near the turning point of the current gyre.

the environment. Neshyba calculates that an average-sized iceberg is thus responsible for a vertical volume transport into the upper layer of the Weddell Sea of 3.3×10^8 cm³ s⁻¹. This is a considerable transport, and the raising of water and nutrients from depth by this mechanism would be of importance in determining the physical and biological properties of the Weddell Sea. The first suggestion, that fresh melt water rises to the surface, and Neshyba's claims that the melt water will have mixed significantly with its salty environment before reaching the surface, cannot both be correct. We show here that both may be in error.

The vital fact neglected in both arguments is that the ocean environment is not only salty, but there is also a salinity gradient in the upper 250 m of most areas of the oceans. For example, data from the Weddell Sea shown in Fig. 1 (taken from Foster and Carmack³) indicate that the salinity increases with depth, as does the temperature in this region. The data indicate further that both the salinity and temperature distribution have a characteristic 'stepped' structure, with layers of well mixed temperature and salinity separated by sharp interfaces in which both properties vary more rapidly. Similarly, off the Californian coast the salinity again has a general increase with depth, while there is an overall decrease in temperature (see, for example, Gregg and Cox⁴, in particular their Fig. 1). We have carried out a series of experiments in which ice is inserted into a salinity gradient, and the preliminary results are reported here.

Iceblocks made from water which had been deaerated under vacuum measuring approximately 20 cm × 10 cm × 3 cm were inserted vertically (see Figs 2-3) into salt-stratified water at room temperature (~23 °C) with constant density gradients of between 1×10^{-3} and 6×10^{-3} g

Fig. 2 Shadowgraph photograph showing the tilted layers and interfaces produced by inserting a block of ice into salt-stratified water at room temperature. (Specific gravity at top of tank 1.00, and at bottom 1.05; depth 26 cm.)

cm^{-3} per cm and surface densities between 1.00 and 1.10 g cm^{-3} .

Adjacent to the ice, melt water at 0°C rises in a thin, generally turbulent boundary layer until its density equals that of the surroundings at the same level. Above the level where these densities are equal the melt water in the boundary layer sinks. In our experiments this level occurs at a density of approximately 1.01 g cm^{-3} (if this exists), although in the ocean, with its typically lower temperature and higher salinity, such a level (where the density of the fresh melt water equals that of its surroundings) is unlikely to occur. The presence of a horizontal temperature gradient imposed upon the existing vertical salinity gradient alters the boundary layer a small distance away from the ice, producing a regular series of tilted convecting layers which grow out into the environment, as shown in Figs 2–4.

These layers exist because of double-diffusive convection, which readily occurs whenever two components of different molecular diffusivities contribute to the density. The general principles governing this form of convection and some applications are discussed by Turner³. Along the bottom of each layer, relatively fresh, cold water acquires heat and some

Fig. 3 An experiment carried out using the same conditions as shown in Fig. 2, but with fluorescein frozen into the ice block, and side illumination. The spread of the dye again shows the layers, but also indicates the distribution of the melt water.

salt across the 'diffusive' interface separating it from the environmental water at the top of the layer below. Thus the melt water becomes progressively lighter and runs uphill as indicated by the upward tilt of the layers seen in Figs 2–3. Along the top of the layers there is an inflow of environmental fluid, which is directly mixed with the melt water only near the ice. In this way a considerable portion of the melt water can be fed into the environment close to the level at which it is produced and very little, if any, rises to the surface.

The melting rate of the ice is controlled by the rate of heat transfer from the environment, and is thus greatly influenced by the circulation that occurs. On a large scale this means that increasing the salinity of the environmental fluid increases the relative buoyancy of the melt water.

Fig. 4 The experimental tank at a later stage of the experiment of Fig. 3, soon after the iceblock had been carefully removed. The volume of dyed water is much greater than that of the ice block, indicating that the melt water mixes with a large volume of salty water and spreads out close to the level at which it is produced; little reaches the surface.

The velocity in the boundary layer thus increases, which results in increased melting. On a smaller scale, the layered motion produces a series of horizontal ridges (see Fig. 5) along the sides of the ice, with the deepest erosion corresponding to the centre of each of the layers, and the ridges to the interfaces between them. In each experiment, the layer size is reasonably uniform with depth and increases with either decreasing density gradient or increasing central salinity. In the laboratory this size is of the order of 1 cm. In the Antarctic, the weaker salinity gradients will tend to make the layers deeper, though this will be counteracted by the smaller horizontal density gradients. The quantitative scaling relations are to be discussed elsewhere.

Further suggestions follow immediately from the results of these experiments. First, the data displayed in Fig. 1b were obtained near the centre of the large gyre which characterises the circulation in the Weddell Sea. This structure differs markedly from that at the edges of the gyre (Fig. 1a) in that it has much stronger temperature and salinity gradients from 50–100m depth, weaker density gradients from 50–500 m and a more clearly defined step structure. We conjecture that this difference is due to the systematic injection of melt water at intermediate depths by icebergs which spend a longer time near the centre of the gyre. The spatial variability of the layering in this region³ is consistent with such a localised mechanism of formation, rather than a more extensive 'one-dimensional' convection process acting over the whole area.

Further measurements of temperature and salinity, made as close as possible to an iceberg in order to detect the layering, would be instructive. It would then be worthwhile

Fig. 5 An oblique view of a melting ice block, taken through the water surface. Note the ridges, caused by the uneven melting associated with the convection in layers.

exploring the structure of the layers as a function of distance from the ice. A direct search for the ridges associated with the variation in rate of melting produced by the convection might also be considered.

Finally, our results imply that those seeking to obtain fresh water from icebergs will have to consider alternative methods which isolate the melt water in some way from the surrounding seawater.

We thank R. Wylde-Browne for his able assistance with the experiments and particularly with the photography. This research was carried out while H.E.H. was a visiting fellow at the Australian National University and was in part supported by grants from the Royal Society and the British Admiralty.

Iceberg sounding by impulse radar

KNOWLEDGE of an iceberg's draft is essential for assessing its risk to underwater installations, in predicting its drift, and for estimating its total bulk. Because of the highly irregular shape of icebergs, it is impossible to estimate an iceberg's draft directly from its above-water dimensions. Large tabular icebergs have been sounded using radio techniques^{1,2}. We report here that estimates of the draft of irregularly-shaped icebergs can also be obtained from the air quickly and accurately using short-pulse radar. A small iceberg in Twillingate Harbour, Newfoundland (49° 40'N, 54° 46'W) was sounded from a helicopter using impulse radar, on 11 June 1977. The result was verified by simultaneous measurement of the iceberg's draft using side-scan sonar.

The impulse radar equipment³, built by Geophysical Survey Systems consists of a control unit and an FM tape recorder, which were mounted in a helicopter, and a transmitter-receiver and antenna assembly, which was slung in a net about 6 m beneath the aircraft. The radiation pattern of the antenna is similar to that of a half-wave dipole. The transmitted signal is a broad-band pulse with a duration of about 20 ns and a centre frequency near 80 MHz. The receiver was set to accept echoes for up to 1.4 μ s, and by sequential sampling of the received signal, an audio-frequency replica trace was constructed and recorded on tape. After sampling, the effective repetition rate was 51.2 scans s⁻¹.

One of the impulse radar records is shown in Fig. 1, taken with the aircraft flying approximately 20 m above sea level. Strong echoes are represented by dark lines; signals received with long delay time are enhanced by a time-gain amplifier. Initial returns are due to reflections of the transmitted pulse between the antenna and the helicopter. The echo from the sea surface is very clear, but, as the iceberg is approached, this echo fades and a faint return from the sharply-peaked top of the iceberg is seen. Reflections from within the iceberg are very clear, although there is no unique bottom echo, since the radar signal reverberates within the iceberg. A set of multiple echoes is received with longer delay time.

To interpret the iceberg draft, the speed of the radar pulse in ice must be known. The speed of electromagnetic waves travelling in a dielectric medium is given by $c\epsilon_r^{-1/2}$, where c is the speed of light in free space, and ϵ_r is the relative dielectric constant of the medium. A dielectric constant of 3.2 was used, giving a velocity of 0.084 m ns⁻¹ of two-way travel time in ice. Ice samples collected from the iceberg surface were polycrystalline, and had a density of 0.938 ± 0.011 Mg m⁻³. These values for density and dielectric constant are consistent with previous work³.

The travel time used to interpret the draft was that from the first subsurface echo that was received directly beneath the centre of the iceberg. This return represents the most direct route through the ice, and it had a consistent multiple. Of course, there is no guarantee that this return came from the deepest subsurface point of the iceberg. The average draft of the iceberg was estimated to be 18.0 ± 0.9 m, with a standard deviation of 0.7 m over 16 passes. The height of the iceberg was also estimated, giving a draft: height ratio of about 4.3:1.

The hyperbolic patterns seen on either side of the iceberg are interpreted as reflections from pulses which entered the upper side of the iceberg, and traversed the iceberg before returning. Their path length in the ice was greater than the direct top-to-bottom path length, and the hyperbolic pattern is caused by the increased path length in the air as the horizontal helicopter-iceberg separation increased. These hyperbolic returns are often stronger than the direct bottom return as a larger proportion of the signal incident on the

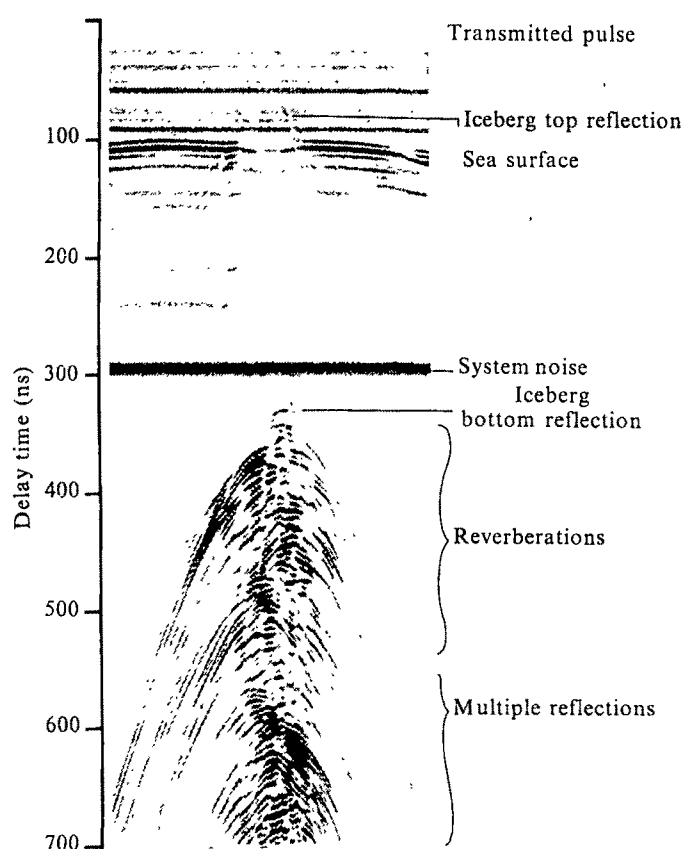

Fig. 1 Impulse radar record taken from a helicopter flying over the iceberg. Horizontal axis is aircraft position; vertical axis is radar echo delay time. Aircraft flew approximately southward during this run.

iceberg entered the iceberg through its flat upper surface than through its sharply peaked top. The hyperbolic returns contain information about the subsurface shape of the iceberg, and this might be better delineated by suitable processing of the data^{4,5}.

An estimate of the attenuation of the radar pulse within the ice was made by comparing the amplitude of the iceberg bottom echo with the amplitude of reflections from the calm sea surface, assuming a normally incident signal on plane interfaces. This assumption results in an upper estimate for attenuation. Using this approach, the attenuation rate (exclusive of spherical spreading) was estimated to be $0.20 \pm 0.02 \text{ dB m}^{-1}$, implying the possibility of sounding icebergs several hundred metres thick. The attenuation rate could easily be an order of magnitude lower, which would be more consistent with previous work on polar ice with few impurities^{2,3,6}. The chlorinity of ice samples taken near the surface of the iceberg was $1-10 \times 10^{-5}$, indicating little contamination of the ice by sea water. No evidence was

Fig. 2 Interpretation, obtained from side-scan sonographs, of iceberg underwater profile, for each of four faces.

seen for random internal scattering due to inhomogeneities, common to radar sounding measurements of temperate glaciers⁷.

Side-scan sonar has been used previously to profile icebergs⁸, by lowering a sonar transducer vertically, at a known rate, from the side of a boat. The sonar system used was built by Klein Associates, and was modified for vertical operation. A model 8A-350 acoustic transceiver, which operates at 100 kHz, and a model 402 towfish, which transmits a $1.75^\circ \times 20^\circ$ fan-shaped beam, were used.

Fig. 3 Iceberg above-water form as it rolled, viewed from the south-west. Lower photograph shows approximate final position of the iceberg during the measurements. This sequence spanned about 3 min.

As the towfish was lowered over the side of a boat, about 10 m away from the iceberg, the sonograph was displayed on a graphic recorder, and manually marked with the length of cable played out. A strong echo was received from the side of the iceberg, and the point at which this echo disappeared on the sonograph record was interpreted as indicating the depth at which the towfish had dropped beneath the lowest point of the iceberg. Interpreted iceberg profiles were made at four faces of the iceberg (Fig. 2). The overall draft of the iceberg was determined to be 18.0 ± 1.5 m.

Although the subsurface form of an iceberg can be obtained using side-looking sonar, this approach has some serious limitations. The technique is operationally very slow, and requires expensive logistic support, including a vessel. It also requires corrections for the tilt angle of the transducer from vertical and for the incident beam reaching grazing angle at the bottom of the iceberg, both of which are often difficult to estimate.

An iceberg's underwater shape clearly affects its stability, with most of an iceberg's ablation occurring beneath the waterline. As the iceberg melts it can become metastable so that only a slight perturbation is needed to initiate rolling. The wake from a small boat caused the iceberg under study to roll through 90° (Fig. 3). The underwater shape and the rolling process are important unknowns in understanding iceberg deterioration.

Although the measurements reported here are for a single, small iceberg, airborne radar shows considerable promise as a quick, safe, and accurate means of sounding icebergs. Interpretation of the radar return may be complicated by reflections from many facets within the iceberg; hence, the technique might be easier to apply to larger icebergs than to smaller ones. It might be most useful in relating the above-water form of icebergs to their subsurface draft on a statistical basis.

We thank T. Ridings, J. Johnstone, W. Winsor and J. Skidmore for assistance; A. Allan for encouragement. We also thank Memorial University Faculty of Engineering for the use of the side-scan sonar system.

Slave–Churchill collision tectonics

THE analogue model^{1–4} of plane indentation⁵ is applied qualitatively here to the proposed collision⁶ of the Slave craton (last major deformation ~ 2,500 Myr ago) and the western Churchill craton (last major deformation ~ 1,740 Myr ago) of the Canadian Shield. The model successfully predicts several large-scale deformational features of the collision zone. McKenzie¹ has drawn an analogy between the collision of the African plate (Arabian shield) with the Eurasian plate and the impact of a hard die on a soft piece of metal. He concluded that when salients

of an approaching continent meet an Andean-type margin of another continent, further lithospheric consumption is not possible due to the buoyancy of continental crust^{1,7} and either the crust of the underthrust continent is thickened, or two or more small plates (such as the Turkish, Aegean and Iranian plates) are formed and are pushed aside to permit further convergence, or both processes occur¹.

Molnar and Tapponnier^{2–4} have presented a similar analogy to explain certain tectonic features of Asia. They believe that the collision of India with Asia is responsible for the tectonic pattern we now see in Asia. Some crustal shortening is attributed to overthrusting in the Himalayas and in Tibet but the greatest amount of shortening is attributed to lateral movement of crustal blocks out of the path of the advancing subcontinent. In their model, India is analogous to a rigid indenter, Asia to a rigid-plastic solid, and large-scale strike-slip faults in Asia correspond to slip lines formed in response to plane indentation. They appealed to differently shaped rigid dies (Fig. 1a, b) in various parts of the collision zone to explain different features of the tectonic pattern of Asia. Of particular interest is the analogy they drew between the boundary of India in the western Himalayas and in Pakistan (Fig. 2a) and a wedge-shaped indenter (Fig. 1b).

A similar analogue model can be used to predict the behaviour of the Slave craton and the type of deformation that the Churchill craton underwent during collision. Here the Slave corresponds to a wedge-shaped rigid indenter, and the underthrust Churchill to a rigid-plastic medium (Figs 1b, 2b). The model predicts at least six major deformational features of the collision zone. These are now examined in turn to determine the success of the model.

According to the model (Fig. 1b) the northern and southern common boundaries of the Slave wedge and Churchill craton should be sinistral and dextral strike-slip faults respectively. The Bathurst and McDonald faults (Fig. 2b), which form the boundaries of the Slave wedge are major sinistral and dextral strike-slip fault systems that extend for hundreds of kilometres. They can be compared with the Quetta–Chaman and Karakoram faults in India (Fig. 2a). The model further predicts that the Slave wedge should behave as a rigid body relative to the Churchill. Hoffman *et al.*⁸ consider that relatively undeformed Archean rocks of the Slave province extend as far south as a wide belt of intensely lineated mylonites that occurs south of the McDonald fault in the Churchill province (Fig. 2b). Because the Slave granites are relatively undeformed and because the mylonites are apparently cut off by the McDonald fault, Hoffman *et al.* regard the mylonites as older than the fault and not genetically related to it. The present model, however, provides an alternative explanation for these relationships in terms of the different responses of the cratons to indentation; the rigid wedge (Slave) suffers relatively little deformation whereas the rigid-plastic medium (Churchill) is deformed intensely by widespread shearing and cataclasis over the areas indicated by the slip lines in Fig. 1b.

As indentation proceeds, crustal shortening is accomplished by local crustal thickening near the apex of the wedge, by sideways motion of crustal blocks (microplates) along strike-slip faults, or by both processes. The boundary between the Slave and Churchill provinces in the apical region is the Thelon metamorphic front⁹. Belts of cataclastic gneiss and mylonite occur in a wide zone roughly parallel to the front within the Churchill province¹⁰ and much of the eastern margin of the Slave is an extensive zone of shearing¹¹. The front is bounded on the Slave side by a regional negative gravity anomaly that is truncated by the Bathurst and McDonald faults and on the Churchill side by a coextensive positive anomaly (Fig. 3a). These paired anomalies have been interpreted as an edge-effect between juxtaposed crustal blocks of different mean density and thickness⁶; the Slave block is regarded as 'normal' crust whereas the Churchill crust is locally thickened and has a somewhat higher than normal density (Fig. 3b). Gibb and Thomas⁶ have interpreted the density discontinuity separating the blocks as a cryptic suture between collided cratons. The apical region of the Slave wedge is thus a wide zone of cataclasis where underthrusting of the Churchill has been inhibited by

Fig. 1 Pattern of slip lines formed in the indentation of a semi-infinite flat rigid-plastic solid (FR-PS) by (a) a flat rigid indenter (FRI) and (b) a wedge-shaped rigid indenter (W-SRI) (modified from refs 1, 3, 5). Small arrows show sense of shear along α and β slip lines. Large arrows indicate direction of motion of indenters and displaced material of rigid-plastic solid. The analogous relationship of the Bathurst (B) and McDonald (M) faults to the models is also indicated.

buoyancy of continental crust resulting in localised crustal thickening as predicted by the model. It can be compared with the Pamir thrust belt in India (Fig. 2a).

Within the Churchill province strike-slip faults bounding microplates that may have developed north and south of the Slave wedge should display dextral and sinistral motion respectively (Figs 1b, 2b). Although the geology of these critical areas is relatively poorly known, a well-developed, unnamed, major fault mapped as a wide mylonite zone¹² (Fig. 2b) along with the Bathurst fault may define the boundaries of a northern microplate pushed sideways from the path of the advancing Slave wedge until such time as suturing was completed. A linear, negative magnetic anomaly coincides with the mylonite zone and extends north towards the coast and south to the Bathurst fault system with a total length of almost 300 km, confirming that the extent of the fault is much greater than shown on maps (Fig. 2b). The model predicts that the mylonite zone should be a dextral transcurrent fault (Fig. 1b) with a role similar to that of the Herat fault in Asia (Fig. 2a). The extension of the McDonald fault to the north-east (Fig. 2b) may be compared with the Talasso-Fergana fault in Asia (Fig. 2a) which has the same position relative to the wedge and the same sense of shearing. The proposed microplate south of the McDonald fault may be delimited to the east by either the sinistral Black Lake or Allan faults (Fig. 2b) and their northerly extensions or perhaps by an as yet unidentified fault corresponding to the Altn Tagh fault in Asia (Fig. 2a). The Black Bay fault is another possible boundary fault; its geometry is consistent with the slip line pattern but its sense of movement is dextral.

North of the Bathurst fault reconnaissance mapping¹² has revealed several mylonite zones but not in sufficient detail to determine the strike-slip fault pattern predicted by slip line field theory (Fig. 1b). In the apical region, however, the effects of indentation are graphically illustrated by faults which dissect the Thelon magnetic high¹³ (Fig. 3c). Here major splays of the Bathurst¹³ and McDonald¹⁴ fault systems correspond to the pattern of slip lines formed by indentation of a flat die (Fig. 1a). Splay faults associated with the Bathurst fault system cut the magnetic high sinistrally¹³ as predicted by theory (β slip lines of Fig. 1a). A second set of faults almost normal to the first corresponds to α slip lines with a dextral sense of movement (Fig. 1a). South of the McDonald fault, the whole area as far south as Lake Athabasca is characterised by complex fault patterns¹⁵ which include wide mylonite zones, anastomosing faults related to the McDonald fault¹⁶ and to other major transcurrent faults, normal faults like those bordering the Nonacho basin¹⁷ and regional thrusts.

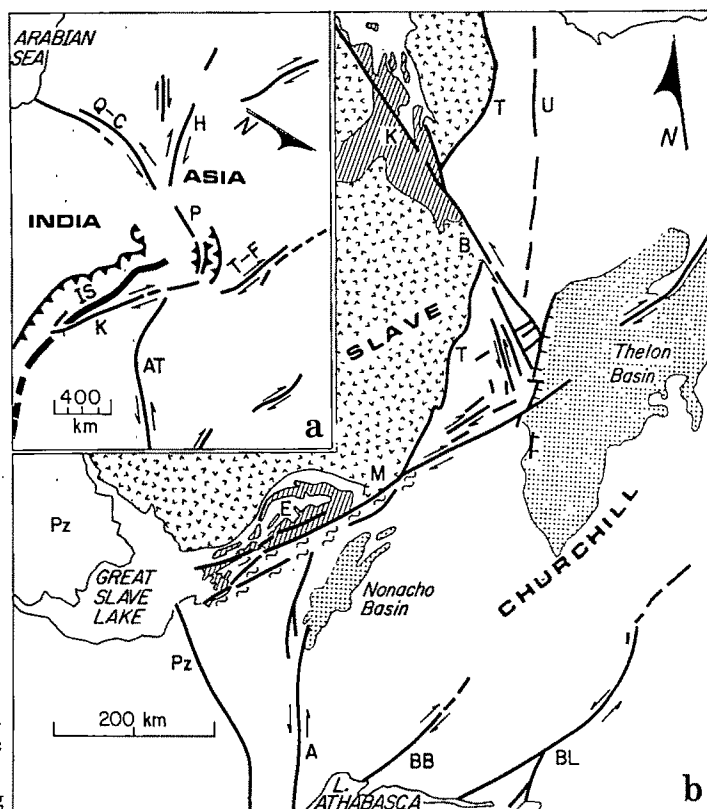

Fig. 2 Comparison of the major tectonic elements of (a) India and Asia in the vicinity of the Pamirs (P) (after ref. 3) with those of (b) the Slave-Churchill boundary zone in Canada (modified in part from refs 12-18). a, Q-C, Quetta-Chaman fault; H, Herat fault; K, Karakoram fault; T-F, Talasso-Fergana fault; AT, Altn Tagh fault; IS, Indus suture. b, B, Bathurst fault; M, McDonald fault; T, Thelon front; U, unnamed mylonite zone and its extensions to north and south; A, Allan fault; BB, Black Bay fault; BL, Black Lake fault; K, Kilohigok basin; E, East Arm foldbelt. Ornament, v pattern, Slave province; waves, mylonite zone; diagonals, Apehian basins; dots, Helikian basins; Pz, Paleozoic cover.

According to the wedge indentation model, rocks of the ancient Churchill continental margin originally at the apical contact region should be squeezed out and transported along the bounding faults of the indenter. Exotic breccias that have proved difficult to explain occur in the East Arm foldbelt in several fault-controlled zones associated with the McDonald fault¹⁸. Breccia fragments include both Apehian sediments and Archean granite and range in size from large blocks tens of metres in length, to 'normal' breccia containing fragments a few centimetres in length set in a finer matrix. A possible explanation for these exotic breccias and other allochthonous fault-bounded blocks in the foldbelt is that they are chaotic fragments of the ancient Churchill

margin and craton that have been transported to their present locations in the Slave-Churchill boundary fault zone during the process of collision (indentation). Similar unexplained exotic breccias occur within the Aphebian Goulbourn Group rocks of the Kilohigok basin in the Bathurst fault zone¹⁹ and may have the same origin. Nappes have been described recently by Hoffman *et al.*⁸ in the East Arm foldbelt. They are up to 70 km long and 10 km wide⁸ and may have been ruptured and deposited during the same process; alternatively they may have been deposited by obduction of basin fill from the south during closure of the diminishing sea between the Slave wedge and Churchill craton. The presence of

compressional structures in the East Arm foldbelt and the juxtaposition, on either side of the foldbelt, of crustal blocks of distinctly different metamorphic history, metamorphic age, and deformational history tend to support a collision model rather than the aulacogen (failed rift) model proposed by Hoffman²⁰ in which tensional features should predominate and bordering cratons are likely to be similar.

These preliminary results suggest that the wedge indentation model or other variants of the indentation model may be useful for predicting deformational features of other proposed collision zones within the Canadian Shield²¹ as originally suggested by Molnar and Tapponnier².

Inbreeding and dispersal in the great tit

IN populations which normally outbreed, matings between close relatives can result in a decrease in the viability and fertility of their offspring. Such inbreeding depression has been shown in a number of laboratory studies of insects¹, birds² and mammals³. We present here the first detailed evidence of inbreeding depression in a natural population and support for the hypothesis⁴ that one function of dispersal between birth and breeding sites is to reduce an individual's chance of inbreeding.

The paucity of long term studies on known individuals has meant that the frequency and consequences of inbreeding in natural populations are virtually unknown. Inbreeding has been reported in the great tit (*Parus major*)^{5,6}, the yellow-eyed penguin (*Megadyptes antipodes*)⁷, the song sparrow (*Melospiza melodia*)⁸, the deer mouse (*Peromyscus maniculatus*)⁹, in addition to probable cases in the gorilla (*Gorilla gorilla*)¹⁰ and olive baboon (*Papio anubis*)¹¹. In all cases, except the great tit⁶, no estimate was made of the relative frequency of inbreeding and the extent of inbreeding depression. Bulmer⁶ made an initial investigation of inbreeding using the great tit data collected from 1964-70 in Wytham Wood near Oxford and we have made a more extensive analysis, using the data collected in the period 1964-75.

From 1964 to 1975 there were 885 pairings in which the identities of both the male and the female were known. Pairs are formed both from birds born in the wood (residents) and from those born outside (immigrants). Details of the study area can be found elsewhere^{12,13}. The 885 pairs consisted of 194 matings between resident males and resident females, 239 between resident males and immigrant females, 158 between immigrant males and resident females and 294 between immigrant males and immigrant females. Of the total number, 13 (1.5%) were inbreeding pairs: five mother-son, seven

brother-sister (each pair from siblings in the same brood) and one aunt-nephew. If we include the same pairs breeding in 2 or more years, the total number of matings was 1,000, of which 16 (1.6%) were inbred. Two mother-son and one brother-sister pair each bred twice. The coefficient of inbreeding is

$$F = [(5 \times 0.25) + (7 \times 0.25) + (1 \times 0.125)] / 885 = 0.0035$$

It is probable that all cases of inbreeding between close relatives have been found⁶. The incompleteness of some of the pedigrees may have meant that a small, but undetected, number of inbreedings may also have occurred between more distant relatives, but such cases would produce only a slight increase in the coefficient of inbreeding.

From figures presented by Richdale⁷, we have also calculated the coefficient of inbreeding in the yellow-eyed penguin. In 244 pairings which produced 490 matings he found three brother-sister, one half brother-half sister and three second cousin cases of inbreeding. The coefficient of inbreeding in this instance is

$$F = [(3 \times 0.25) + (1 \times 0.125) + (3 \times 0.0156)] / 244 = 0.0037$$

The frequency of close inbreeding (coefficient of kinship ≥ 0.125 (ref. 14)) is 1.6%. The figures are close to those found in the great tit: both species exhibit low levels of dispersal.

In laboratory studies the timing of reproduction, litter size, infant or fledging mortality^{2,3} and offspring viability and fertility^{3,15} may all be affected adversely by inbreeding. The laying date, clutch size, fledging success and number of offspring subsequently recorded breeding in the wood for all matings between relatives in the great tit are shown in Table 1. We have also calculated the dispersal distance from natal to breeding sites by all males, and those females mated to their brothers. In the cases of mothers and aunt mating with sons and nephew respectively, the appropriate measure of dispersal was the distance from previous outbreeding site to the subsequent inbreeding locality. For all these measures we have calculated the expected values from comparable outbred matings in which both parents were known (all second broods and relays have been excluded). Since there are yearly and age variations in laying date, clutch size¹² and dispersal (our work in preparation),

expected values are for each age-year category in question. We have only distinguished between first year and adult age classes, since sample sizes would otherwise have been small. The expected values for nesting success and the number subsequently recorded breeding in the wood have been calculated from the whole period 1964-75. We have excluded from the analysis all cases, in both inbreeding and outbreeding pairs, where breeding success was affected by predation, disturbance or experimental manipulation of brood size. For example, a great spotted woodpecker (*Dendrocopos major*) drilled a hole in the side of a nest box used by a mother-son pair in 1969. The incident occurred at hatching time and no offspring subsequently fledged; this pair has not been included in the calculation of nestling mortality.

On the three occasions when related birds bred in more than one year we have assumed that variables, such as laying date, are not independent measures. Consequently, in the analysis, we have averaged the observed and expected values for the 2 years.

The coefficient of kinship between mother and son is 0.25, as is, on average, that between full sibs, whereas that between aunt and nephew is 0.125. In our analysis we have included the latter example even though inbreeding depression would be expected to be less severe.

There is no evidence that inbreeding pairs produce smaller clutches than outbreeders (Wilcoxon test, $T = 32$, $n = 13$). Unexpectedly, however, the females mated with close relatives commenced laying before other females ($T = 15$, $n = 13$, $P < 0.05$). The reason for earlier laying is unknown, but may be connected with dispersal distance (our work in preparation). The result differs substantially from the laboratory study of *Peromyscus maniculatus*, in which siblings induced to mate, showed a delayed onset of reproduction when compared with unrelated pairs³.

Nestling mortality is higher among inbreeding than among outbreeding pairs ($T = 23$, $n = 15$, $P < 0.05$). We cannot distinguish between eggs which failed to hatch and offspring which died after hatching but before fledging. We refer collectively to the mortality as nestling mortality, which was, on average, 27.7% among inbreeders, whereas the expected mortality from equivalent sized clutches from outbreeders would be 16.2%.

Of the 86 inbred offspring which successfully fledged from mother-son and full sibling matings, five (5.8%) were subse-

Observed (O) and expected values (E) for inbreeding pairs 1964-75. Pairs breeding in more than 1 yr are bracketed together. Two brother-sister pairs recorded in 1977 were used only in the analysis of nestling mortality.

* Breeding disturbed by woodpecker at time of hatching.

Fig. 1 Distance dispersed by outbreeding individuals between natal site and site of first breeding. The distance localities of inbreeding are marked for males only, when mated to mothers and aunt, and for both males and females, moving the same distance, in brother-sister pairs. Dispersal: , males; ————, females. Inbreeding: Δ , mother-son; \blacktriangle , brother-sister; \blacklozenge , aunt-nephew.

quently recovered breeding in the wood. If we include the one produced by the aunt-nephew pair, six (6.4%) returned from 94 offspring. The expected number from normal broods were respectively 8.56 (10.0%) and 9.40 (10.0%). If we assume that the number of recoveries fits a Poisson distribution, then the probabilities of obtaining five or less from 86 and six or less from 94 fledglings are 0.145 and 0.174 respectively. Mortality after fledging is not significantly greater than expected.

The six inbred offspring (three males and three females) subsequently outbred and produced an average clutch of eight eggs. The nestling mortality of their offspring was 16.7%. None of the offspring of mother-son or brother-sister pairs survived longer than one breeding season, whereas that of the aunt-nephew pair survived 2 years.

The distance dispersed between natal and breeding site may affect the chances of mating with a close relative. The patterns of dispersal of normal juvenile males and females, together with the locations of inbreeding are shown in Fig. 1. Females disperse further than males in their first year⁶; but subsequently, there is little movement and individuals tend to retain the same territory from one year to the next (our work in preparation). These patterns of dispersal lead to the expectation that sons mating with their mothers would have dispersed substantially less than expected. In sibling matings, brothers should move more than the expected median distance or sisters less than expected, or both. These predictions are supported by the data, although formal testing is inappropriate because of the lack of independence of dispersal between related inbreeding individuals. On average, sons mated with their mothers moved only 67 m from natal to breeding site, 85% less than the expected distance (461 m). Males mated to their sisters dispersed 13.5% more than expected, 619 m as opposed to 545 m, whereas sisters moved less than expected (24%), 619 m rather than 812 m.

From the distribution of dispersals it is possible to calculate the expected number of inbreedings from the model produced by Bulmer⁶. For close relatives these are: mother-son, 6.2 (observed 5); brother-sister, 7.35 (observed 7); and father-daughter, 2.2 (observed 0). More examples are necessary, before it is possible to estimate whether fewer inbreedings are occurring than would be expected.

We have shown that inbreeding pairs have a lower breeding success, resulting from higher nesting mortality, than normal pairs and that the chances of inbreeding vary with dispersal distance. Since the avoidance of such matings is one factor influencing dispersal, it is possible that the asymmetry in movement between males and females in many sedentary species

is maintained by the detrimental effects of inbreeding^{1,16-18}.

We are grateful to Tony Martin and Peter Croydon for computer programming support. We thank Michael Bulmer, Tim Clutton-Brock and members of the Population Biology Group at Sussex for comments, and John Maynard Smith for much help and encouragement. This work was supported by the SRC.

Cortical magnification factor predicts the photopic contrast sensitivity of peripheral vision

THE area of visual cortex devoted to the analysis of a constant-size region in the visual field diminishes progressively for more peripheral locations. The change is described quantitatively by the cortical magnification factor, which indicates the linear extent of cortex in mm corresponding to one degree of visual angle at various eccentricities (angular distances from the middle fovea). The human cortical magnification factor has been estimated by Cowey and Rolls¹ from the data of Brindley and Lewin², who mapped the phosphenes (sensations of light) caused in the lower nasal visual field by electrical stimulation of the human visual cortex. Building on these results, we have studied the spatial contrast sensitivity functions in man at various eccentricities. We used two methods: in one the retinal image sizes of the test gratings were kept similar at different eccentricities and in the other, the calculated sizes of cortical projections of the test gratings were made similar at different locations. Our results indicate that peripheral contrast sensitivity and acuity are inferior to foveal performance, because of the diminished cortical projection area.

Four experienced subjects fixated a small point of light binocularly in a dark room; a bite board aided steady fixation. The contrast sensitivity at various eccentricities along the nasal horizontal and inferior vertical visual-field meridians of the right eye was measured by determining the inverse of the threshold contrast for each of a series of sinusoidal gratings. The gratings were generated on a white cathode-ray screen³, masked to expose only half of a round field, 16 cm in original diameter (see inset, Fig. 1a). The screen was perpendicular to the visual axis if viewed directly and at the same distance as the fixation point; the screen was not visible to the left eye.

The average luminance of the screen was continually

11 cd m^{-2} and the diameter of the natural pupil varied from 6 to 7 mm. (No artificial pupil was used because it limits the visual field.) The photopic average retinal illuminance was thus about 365 Trol (1 troland = $1 \text{ cd m}^{-2} \times \text{pupillary area in mm}^2$). On our display this corresponds to about 1,030 scotopic Trol, indicating a photopic adaptation level.

Thresholds were determined by using a computer-controlled forced-choice method: the subject received two sound signals and had to decide during which signal a grating was presented. Another sound indicated the wrong choices. After each block of four consecutive correct responses, contrast was decreased by 2 dB and every wrong choice led to a contrast increment of 2 dB: the contrast required for a probability of 0.84 of correct response was estimated from the turning points as described by Wetherill and Levitt⁴. The critical stimulus to be detected was a stationary vertical grating with a non-zero contrast for 0.5 s; the control stimulus was otherwise identical but had a zero contrast. To avoid the bias caused by the Troxler effect (fading of stimuli in peripheral vision) the subject initiated each threshold trial only when the display was clearly visible. Control experiments showed that results essentially similar to those of the detection method are obtained from a two-choice recognition of grating orientation or direction of movement.

Figure 1 shows the results for subject V.V. in the lower half of the vertical meridian; the results of other subjects and of the nasal horizontal visual field were similar. In the experiments of Fig. 1a the display was viewed at a constant distance of 458 cm. The retinal images of the gratings subtended $1 \times 2^\circ$. At increasing eccentricities, contrast sensitivity and visual acuity (assessed from the resolution of high-contrast gratings) decreased as similar decelerating functions of eccentricity.

Figure 1b presents results for the same eccentricities, but in this case both the spatial frequency and the size of the gratings were scaled by the inverse of the cortical magnification factor estimated from the points calculated by Cowey and Rolls¹. Thus, the cortical topographical representations of the gratings became equal in size at various eccentricities. For the series of eccentricities: 0, 1.5, 4, 7.5, 14 and 30° the following magnification factors were assumed: 7.75,

5.25, 3.44, 2.31, 1.24 and 0.49 mm. The scaling of gratings by the inverses of these values was accomplished by keeping the gratings constant and moving the subject closer to the display; the effects of the changes of accommodation on acuity were partially compensated by corrective lenses. The viewing distances for the semicircular gratings with radius 8 cm were 458, 312, 204, 137, 73.3 and 28.3 cm. Thus the gratings subtended $1 \times 2^\circ$ at $E=0$, and $15.8 \times 31.6^\circ$ at $E=30^\circ$, with corresponding intermediate retinal sizes. Assuming that the magnification factors were correct, the crescent-shaped cortical projection fields had a constant size of about $7.75 \times 15.5 \text{ mm}$ and the fields stimulated at neighbouring eccentricities were tangential to each other.

After scaling, the widely separate contrast sensitivity functions of different eccentricities collapsed to an apparently single function, as in Fig. 1b. This is surprising, because different types of retinal ganglion cells may dominate in peripheral and foveal visual systems, and the projections reach several locations in the brain⁵. A good correlation between conventional measures of visual acuity and the magnification factor^{1,6} can be explained by postulating a homogeneous detection system subserving acuity, but there is evidence that different types of mechanisms mediate the detection of low and high retinal spatial frequencies⁷.

A minor deviation from the unity of the scaled functions occurred at high spatial frequencies (Fig. 1c), but this was expected for optical reasons. The optical limitations of contrast transfer with a pupil size of 6–7 mm are considerable at high retinal spatial frequencies, but they should not affect the transfer of low retinal spatial frequencies⁸ that represent high 'cortical' spatial frequencies in peripheral vision. Figure 1c shows that sensitivity to the highest 'cortical' spatial frequencies improves somewhat at greater eccentricities, as would be expected if optical factors limited performance at small eccentricities. The small overall decrease of sensitivity from $E=0^\circ$ to $E=1.5^\circ$ reflects the Troxler effect and also our uncertainty regarding the exact value of the foveal magnification factor.

We conclude that the foveal contrast sensitivity function can be generalised for any part of the visual field when two structurally determined adjustments are made: one is based

Fig. 1 Contrast sensitivity as a function of spatial frequency and eccentricity (E) in the lower visual field. *a*, The retinal images of various sinusoidal test gratings were similar at different eccentricities as shown in the inset. Spatial frequency indicates the bar density of gratings in cycles per degree of visual angle and eccentricity refers to the angular distance between the fixation point (F) and the nearest edge of the semicircular vertical grating. Curves represent values of E as follows: \circ , 0° ; \triangle , 1.5° ; \square , 4° ; \diamond , 7.5° ; ∇ , 14° ; \blacksquare , 30° . *b*, Cortical projections of the test gratings were similar at different locations. The symbols are as in *a* regarding eccentricity in the visual field. Spatial frequency indicates the estimated bar density in cycles per mm on the primary visual cortex. *c*, Part of the data of *b* replotted to reveal the expected improvement of sensitivity as a function of E at high cortical spatial frequencies.

on the cortical magnification factor and the other on the modulation transfer function of the eye optics. The result suggests that, using suitable temporal conditions, a picture can be made equally visible at any eccentricity by scaling its size by the magnification factor, because the contrast sensitivity function represents the spatial modulation transfer function of the visual system for near-threshold contrasts. The results by Anstis⁹ on the recognition of letters in peripheral vision agree with this generalisation.

The invariance of the photopic contrast sensitivity functions of different but equally large regions of the visual cortex indicates a striking functional homogeneity of image processing machinery at central levels of the visual system. This functional homogeneity is not normally evident because it is masked by various early transformations of the signals entering the cortex.

Is *Acanthaster planci* an *r*-strategist?

THE debate over the cause of plagues of the crown-of-thorns starfish, *Acanthaster planci*, has been as long as the plagues themselves (for reviews see refs 1-3). Most recently, two lines of reasoning based on ecological concepts have been used to suggest that the causes of the population explosions should be sought in some abnormal event, and thus man has been implicated²⁻⁴. I believe that a more detailed consideration of the ecology of *A. planci* does not support this view; rather, it suggests violent population fluctuations without the assistance of man's activities.

It has been predicted² that complex ecosystems such as coral reefs should be resistant to perturbations because of the supposed stabilising effect of high trophic complexity². It is now more widely thought⁶⁻⁸ that the stability often apparent is a consequence of a highly predictable environment, which, it is believed, on coral reefs² allows a great diversity of organisms to specialise on the large number of spatial and biotic niches created there. Such specialised species are characterised by small, stable population sizes and low reproductive rates, and are long-lived.

Grassale's descriptive framework⁷ coincides with Pianka's visualisation of an *r*-*K* continuum⁸, the two extremes representing opposing bionomic strategies for survival in the face of natural selection: *r*-strategist species (or 'opportunists'^{7,10}) tend to exploit unpredictable and/or

short-lived habitats¹¹ by devoting energy and resources to maximising reproductive potential; *K*-selected species (or 'specialists'⁷) exhibit conservative strategies for survival in predictable environments, and are adapted against pressures from predators and inter-specific competition.

Examining some of the important sessile components of the coral reef ecosystem within this framework, it seems that most corals¹² and sponges¹³, and several other organisms¹⁴ exhibit conservative strategies in view of their massive size, long life, and adaptations for inter-specific competition, although some¹⁵ are adapted to exploiting unpredictable habitats.

Where does *A. planci* fit into this picture? Its bionomic strategy is indicated by features of its ecology and life history⁹ which are shown in Table 1. There are several other coral reef echinoderms whose population distributions, like that of *A. planci*, are patchy but locally abundant, and they have also been examined within this framework, with the limited data available.

A. planci has probably a greater range within the coral reef environment than any other echinoderm, being found virtually wherever there is coral. Most other echinoderms are restricted by their food requirements to narrow zones. Studies in the Red Sea³ have indicated some density-dependent predation by fish, but it seems that when population densities become very high, as on the Great Barrier Reef², they escape the control of predators; migration then becomes important. Population sizes vary markedly in time and place¹⁻³; normal population densities are rather low, and 'dense populations' are uncommon¹⁶. Dense populations can persist aided by the virtual absence of inter-specific competition for coral prey from other reef inhabitants: most fish or other coral predators only graze polyps sub-lethally or kill small parts of colonies^{17,18}. None, except perhaps donkey-fish (*Bulbometopon muricatus*) locally (my observations), would affect significantly the food available to *A. planci*: it is apparently exploiting what is virtually an ecological vacuum.

Whereas coral is killed by *A. planci* and takes some years to be replaced, the nature of the food resources of many other common coral reef echinoderms (for example, the starfish *Linckia multiflora* (my observations) and *L. laevigata*¹⁹—substrate feeders, primarily on coralline algae, or the holothuroid *Holothuria atra*—a sediment feeder²⁰) is such that it is continuously being renewed: in their more restricted zones, they compete intra- and inter-specifically for food, near the carrying capacity of their environment. Thus, although the potential for rapid increase in population numbers is present in many coral reef echinoderms, by virtue of the large numbers of larvae produced, adult numbers of most species would seem to be limited by restricted zonation and food availability.

By contrast, *A. planci* feeds selectively at low densities, and when its population density increases, it adapts to unavailability of preferred species²¹, feeding on all scleractinian corals^{1,2}. Also, being relatively mobile, it may exploit extensive areas of reef when its food supply becomes locally depleted², and in these ways it overcomes the problem of intra-specific competition for food.

Table 1 shows that many of its characteristics indicate *A. planci* to be strongly *r*-selected, while other common coral-reef echinoderms exhibit more moderate strategies. But some aspects of *A. planci*'s reproductive strategy, being different from those predicted for *r*-selected terrestrial animals, seem to contradict this view. Upon examination, it becomes clear that different considerations must be applied. We may predict that *r*-selection would favour the production of large numbers of larvae, and most of the commoner species of coral reef asteroids, including *A. planci*, produce many small, planktotrophic, pelagic larvae²². Their survival, however, is probably very

Table 1 Bionomic strategy of *Acanthaster planci* and other common coral reef echinoderms as indicated by life-history characteristics

Correlates of <i>r</i> - and <i>K</i> -selection*	Characteristics of <i>A. planci</i>	Strategy indicated <i>r</i> <i>K</i>	Other common coral reef echinoderms†	Strategy indicated <i>r</i> <i>K</i>
Variability/predictability of environment	Most zones on coral reefs, 1–50 m depth	+	Predictable, restricted zonation	+
Mortality	Density-dependent at low densities, but escapes this control at higher densities; migration important	+	Not known	—
Survivorship	Extensive mortality of larvae	+	Extensive mortality of larvae	+
Population size:				
—variability in time	Variable	+	Less variable than <i>A. planci</i> ?	?
—relation to carrying capacity	Usually low	+	Often high	+
—saturation of community	Ecological vacuum	+	More saturated	+
—recolonisation	Migration of larvae important	?	Larvae migrate; asexual reproduction occurs in some species	?
Competition:				
—inter-specific	Negligible	+	Varies with species	—
—intra-specific	Low except at very high densities	+	Limits numbers locally	—
Characteristics predicted as favoured by selection:				
—rate of development	Fast	+	Relatively slow	+
— r_{max}	Potentially very high	+	Potentially very high	+
—age of sexual maturity	1–3 yr		Not known, but probably comparable	+
—body size	Large compared to other coral reef echinoderms		Varies with species, but all possess anti-predator defences	+
—reproductive strategy	Repeated		Repeated	+
Longevity	8 yr		Not known, but probably comparable	+

Data sources available from author. +, Denotes clearly indicated *r* or *K* strategy; ?, strategy not clear.

*After Pianka⁹.

†Details of individual species are omitted for sake of brevity. Actual species compared are: *Culcita novaeguineae*, *Linckia multiflora*, *L. laevigata*¹⁸, *Diadema setosum* and *Holothuria atra*¹⁹.

uncertain^{23,24}, particularly in the case of *A. planci*, whose high survival rates of larvae may result from unusual levels of water salinity and temperature and food supply (ref. 25 and R. Pearson quoted in ref. 6). The uncertainty in recruitment of juveniles must be counteracted by a shift towards *K*-selection in the adult, reflected in increased longevity, as demonstrated in some marine fishes²⁷: in *A. planci* the life span is believed to be about eight years²⁸. Anti-predator defences (which complement increased longevity) are also present in most common coral reef echinoderms; *A. planci* has spines and a cryptic behaviour, as do many echinoids, and other asteroids have tough skins or heavily-calcified skeletons²². Large size may act in the same way¹¹.

It would be unrealistic to attempt to model mathematically the population dynamics resulting from the bionomic strategy of *A. planci* as outlined above, owing to its apparently 'fugitive' nature (local populations usually have a unimodal age distribution²⁴).

Clearly *A. planci* is not a 'classical' *r*-strategist in the sense of having an unstable or short-lived habitat, but its life-history characteristics indicate a coherent strategy for exploiting what is, surprisingly, a virtual ecological vacuum. In some ways its strategy resembles that of certain insect pests, for example, the spruce budworm²⁹, which conform broadly to *r*-strategies, but exploit longer-lived habitats.

In view of the very high reproductive potential (r_{max}) and the possibly long period before environmental conditions favour massive larval survival, the large fluctuations of local populations which characterise *r*-strategists¹¹ can only be exaggerated in the case of *A. planci*. Thus it is inappropriate to regard the low population levels usually observed^{2,3,16} as 'normal' and high population levels as 'abnormal': periodic plagues are inherent to this mode of living and may well be necessary for survival of the species. It is unfortunate for many fish and other reef inhabitants that such plagues result in the destruction of their habitat³⁰—the effects are comparable to those of destroying the canopy of a tropical rain forest. Coral reefs

are also valuable to man, and it is reflection of his subjective viewpoint as a *K*-strategist, striving to maintain his resources, that the terms 'plague' and 'population explosion' tend to be imbued with emotion.

This paper arose from work carried out during the crown-of-thorns research project funded by the Ministry of Overseas Development. I thank John Lawton and Rupert Ormond for stimulating discussions.

Requirement for cell differentiation in *Dictyostelium discoideum*

THE generation of cell diversity during the development of multicellular organisms involves a series of decisions between alternative pathways of differentiation^{1,2}. In many instances the fate of a cell depends on its position, so that pattern formation and cell differentiation can become facets of the same process³. These phenomena occur in a simple form in the slime mould *Dictyostelium discoideum* where there are only two major pathways of differentiation—one leading to stalk cells and the other to spores. On starvation the individual amoebae aggregate chemotactically to form multicellular masses. Somewhat later the aggregates can be shown to consist of two distinct cell types: prestalk cells which are localised in the anterior and prespore cells in the posterior of the migrating slug⁴. We are interested in how the formation of these cell types is controlled. One approach to this problem involves experimentally inducing differentiation of cells that are somehow prevented from completing normal development. Starving cells plated on agar with a Cellophane overlay aggregate but remain constrained as a monolayer and do not progress to stalk or spore. But addition of 1–5 mM cyclic AMP to the agar results in efficient induction of stalk cell formation provided that a high cell density is used^{5–7}. At low cell density stalk cells do not form unless a low-molecular weight

factor, released by cells at high density, is also provided⁷. We show here that although no mature spores form in conditions of high cell density giving a high yield of stalk cells large numbers of prespore cells do appear. Many of these later transform into stalk cells. Prespore cells do not arise at low density but the density requirement for prespore cell formation, unlike that of stalk cells, cannot be efficiently replaced by the low-molecular weight factor. Five mutants isolated by virtue of their ability to form mature spores under Cellophane likewise do not form spores at low cell density even in the presence of the 'helping' factor. Thus entry of developing *Dictyostelium* cells into the prespore pathway apparently requires some cell interaction different from or additional to that required for entry into the stalk pathway.

Our initial observations, made by electron microscopy, were concerned with the induction of prespore vacuoles (PSVs), which most workers consider to be specific markers of prespore cells^{8–12}. HMI cells were plated at high cell density on agar and overlaid with Cellophane as described in the legend to Fig. 1. In the absence of added cyclic AMP few PSVs and no stalk cells were observed (Fig. 1). When 5 mM cyclic AMP was included in the agar, large numbers of PSVs were induced. They first appeared by 15 h of induction, reached a peak number by 24 h and thereafter declined in numbers as mature stalk cells accumulated. The latter were never seen to contain a PSV.

The experiment described above was rather time consuming and so in the following experiments we identified prespore cells by their specific fluorescent staining with absorbed anti-spore serum^{13,14}. Figure 2b again demonstrates the dramatic induction of prespore cells by 5 mM cyclic AMP at high cell density. This result is in close qualitative agreement with that obtained by electron microscopy. Precedents for these results are to be found in the reports of the occurrence (but not the induction) of prespore cells in the presence of 1 mM cyclic AMP^{15,16}. The kinetics of prespore induction shown in Figs 1 and 2b suggest that

Fig. 1 Induction of prespore vacuoles and stalk cells by cyclic AMP in cells plated at high density under Cellophane. ○, Prespore vacuoles, no cyclic AMP; □, stalk cells, no cyclic AMP; ●, prespore vacuoles + cyclic AMP; ■, stalk cells + cyclic AMP. HMI cells (HMI is an acriflavin resistant strain derived from V12 M2) were grown on SM agar with *Klebsiella aerogenes* and collected in sterile KK_2 buffer (16.5 mM, KH_2PO_4 , 3.8 mM K_2HPO_4 , 2 mM MgSO_4 , pH ~ 6.2) with 60 mM KCl added. They were pelleted at 200g for 3 min, washed three times in KK_2 and finally once in 5% Bonner's salts (100% is 0.6 g l^{-1} NaCl, 0.75 g l^{-1} KCl, 0.3 g l^{-1} CaCl_2). Cells at a density of $2.5 \times 10^5 \text{ cm}^{-2}$ were spread on 2 ml of 1.5% agar (Oxoid L28) containing 5% Bonner's salts, 250 $\mu\text{g ml}^{-1}$ streptomycin with or without 5 mM cyclic AMP, in a 5 cm Petri dish. Washed, sterile Cellophane (slit Visking dialysis tubing) held in perspex stretchers (each consisting of an inner ring fitting tightly into an outer one) was placed over the cells and air bubbles excluded. At the stated times of starvation the central area of agar and Cellophane was cut out and the cells fixed *in situ* with ice-cold fresh fixative (10 mM sodium-cacodylate, 0.5% OsO_4 , 0.5% glutaraldehyde, 1 mM MgCl_2 , 1 mM CaCl_2 , pH 6.8). After 20–30 min the cells were collected, washed three times with 10 mM sodium cacodylate, pH 6.8 and dehydrated in graded alcohols. The specimens were then infiltrated in acetone for 1 h, then in a 1:1 mixture of acetone and Spurr's resin for at least 6 h and finally polymerised in Spurr's resin at 60 °C for 24 h. Sections were stained with lead citrate and uranyl acetate and photographs taken of random fields of cells with a Siemens Elmiskop 1 electron microscope. Prespore vacuoles were seen in 28%, 37%, 26%, 2% and 4% of the cell profiles at 15, 20, 26, 37 and 52 h respectively of induction with cyclic AMP.

Fig. 2 Induction of prespore and stalk cells by cyclic AMP at low (a) or high (b) cell density. ○, Prespore cells, no cyclic AMP; □, stalk cells, no cyclic AMP; ●, prespore cells + cyclic AMP; ■, stalk cells + cyclic AMP. HMI cells were prepared and plated as described in Fig. 1. Those at high density ($2.5 \times 10^5 \text{ cm}^{-2}$) were overlaid with Cellophane but those at low ($5 \times 10^3 \text{ cm}^{-2}$) were not. At the stated times cells at high density were collected in KK_2 and disaggregated with Pronase/British anti-lewisite (BAL)¹³. Those at low density were detached by swirling in KK_2 lacking Mg^{2+} and then pelleted in siliconised centrifuge tubes for 10 min at 1,000g. In both cases the cells were then fixed in 60% methanol and fluorescently stained using absorbed anti-spore serum by a modification¹⁴ of the method of Hayashi and Takeuchi¹³. Cells were examined in a Zeiss Photomicroscope III equipped for epi-fluorescence.

Fig. 3 Stalk and lack of prespore cell differentiation in cells at low density adjacent to high density 'helper' cells. ○, Prespore cells in low density cells over 'helper'; △, prespore cells in low density cells alone; □, stalk cells in low density cells over 'helper'; ●, prespore cells in 'helper'; ■, stalk cells in 'helper'. HMI cells were collected and plated on 5 mM cyclic AMP agar at a density of $2.5 \times 10^5 \text{ cm}^{-2}$ as described in Fig. 1. These 'helper' cells were overlaid with thin Cellophane (325 P, British Cellophane) held in a stretcher. More cells at low density (10^3 cm^{-2}) were then spread over the Cellophane. In control plates the 'helper' cells were omitted. At various times a cover slip was placed on the upper layer of cells and stalk cells scored above and below the Cellophane by microscopy. The low density cells were then detached from the Cellophane by swirling for 10 min with 50 mM Tris, 0.1% Pronase, 25 mM BAL pH 7.0¹³ and pelleted in siliconised centrifuge tubes at 1,000g for 10 min. 'Helper' cells were collected and both sets of cells stained as described in Fig. 2. The recovery of low density cells was normally 5–30% of those plated. Several controls indicate that there was not a selective loss of prespore cells during cell collection. First, similar results were obtained when cells were detached using the Pronase/BAL mixture diluted 1:10 or when they were scraped off in KK_2 and when they were pelleted at $\sim 10,000g$ for 30 s in a microfuge. Second, disaggregated high density cells, plated at low density could be recovered after 1 h with an efficiency of 14–50%. The losses occurring during cell collection did not in this case significantly change the proportion of prespore cells.

many must eventually transform into stalk cells. Support for this view comes from electron microscopic observations of cells taken at later times which show that many PSVs are in the process of breaking down, in a way resembling that described as occurring during the 'de-differentiation' of isolated prespore cells¹⁷. Such a transformation is also consistent with the observations of Town

and Stanford¹⁸ that prespore cells taken from slugs produce a high proportion of stalk cells (but no spores) in similar conditions.

As stalk cells are not inducible by cyclic AMP at low cell density we wondered if the same would be true for prespore cells. Figure 2a shows that this is indeed the case. From this result we conclude that a cell interaction must also be involved in the induction of prespore cells. We showed previously that stalk cell formation by cells at low density ('tester cells') was stimulated by the presence of a high density layer of cells ('helper cells') separated from them by a Cellophane membrane⁷. It was of interest therefore to see if the same was true for the formation of prespore cells. The results of a 'helper' experiment of this type, in which we assayed for stalk and prespore cells, is shown in Fig. 3. Stalk cells are induced in the helper and tester cells with near identical efficiency and kinetics. This is not true for prespore cells. Although a slight induction of prespore cells is consistently observed in the tester cells (compared to low density controls) it is much lower than in the helper cells themselves. Evidently the requirements for induction of prespore cells differs in some way from those for stalk cells.

In the light of these results it is apparent that the failure of wild-type amoebae to form spores when incubated with cyclic AMP under Cellophane at high cell density is not due to their failure to enter the prespore pathway but rather to some block in the maturation of prespore cells. Mutants can be isolated that do form spores in such conditions⁷. These mutants have presumably overcome the unknown block to spore maturation but might be expected to show the same requirement as wild-type amoebae for entry into the prespore pathway. We have, therefore, examined the ability of low density preparations of such strains to be helped to differentiate into stalk and spore cells by high density cells separated from them by a sheet of Cellophane. At the densities used the low density tester cells gave on their own 0–3% stalk cells and no spores. The results for five mutant strains presented in Table 1 show that as expected each is efficiently helped to make stalk cells but not to make spores.

From Table 1 it is evident that there is some stimulation of spore formation by the helper cells, especially when the density of the tester cells was $5 \times 10^3 \text{ cm}^{-2}$, the same density as used previously⁷. We have found (data not shown) that the efficiency of helping is not improved by using Cellophane treated with zinc chloride to increase its porosity. Further we have noted consistently that the spores formed as a result of helping are almost invariably very close to other cells, whereas most of the stalk cells are isolated (Table 1). Both these observations indicate that one of the requirements for entry into the prespore pathway involves a short-range cellular interaction, not required for stalk cell formation. The small stimulation of spore formation by helper cells is consistent with the idea that a low-molecular weight factor is required for both pathways of differentiation.

In conclusion, our results show that in appropriate conditions exogenous cyclic AMP can induce the formation of stalk cells and also the formation of prespore cells or even of mature spores.

Table 1 Enhancement of stalk and spore cell differentiation in low density mutant cells by the same cells at high density

Strain	% Differentiated cell type observed					
	Above cellophane $10^3 \text{ cells cm}^{-2}$			Below cellophane $2.5 \times 10^5 \text{ cells cm}^{-2}$		
	Total	Stalk	Isolated (as % of stalk)	Total	Stalk	Spore
HM9	15.5		90	0	11.9	26.7
HM9*	18.0		49	1.3	14.6	22.2
HM13	36.5		79	0.5	21.5	37.4
HM15	18.2		93	0	27.0	22.3
HM16	15.6		68	0	24.5	8.1
HM18	45.7		65	3.3	44.5	29

Cells of the mutants were collected as described in Fig. 1. High density cells were plated directly onto 5 mM cyclic AMP agar and overlaid with thin Cellophane as in Fig. 3. Cells of the same strain were spread on top at low density. After 3 d incubation at 22 °C a cover slip was placed on the top layer of cells and the cells scored above and below the Cellophane by microscopy. Strains HM13, 15, 16 and 18 were obtained by mutagenesis and selection from HM2 (a cobalt resistant strain temperature-sensitive for growth derived from HMI; R.R.K. & J. Trent, unpublished). Strain HM9 is clone 27 of the strain previously called *sci-1*.

*HM9 cells above Cellophane at a density of $5 \times 10^3 \text{ cm}^{-2}$.

Since cells under Cellophane become aggregation competent in the absence of cyclic AMP (R.R.K., unpublished observations) there must be a requirement for cyclic AMP in both pathways of differentiation beyond the stage of aggregation competence. We therefore regard with caution the idea that levels of cyclic AMP control the pattern of differentiation in *Dictyostelium*^{19,20}. We have, however, identified different requirements for the induction of stalk cells and of prespore cells (in the wild type) or spores (in the mutants). These differences could play a key part in controlling the pattern of differentiation in normal development.

We thank Dr David Forman for producing the antibody, James Vernon and Jennifer Trent for assistance and Dr Julian Gross for helpful discussions.

Unintegrated ribosomal genes and their relation to position effect variegation in *Drosophila melanogaster*

THE variegated expression of genes is most often associated with a chromosomal rearrangement having one or both breakpoints within a heterochromatic region¹⁻³ and as a result, the genes lying near the breakpoint are usually suppressed. In *Drosophila melanogaster*, the genes coding for ribosomal RNA (rRNA) at the nucleolus organiser region are also situated in heterochromatin⁴. Ribosomal genes which are not integrated into the DNA of the chromosome have been found in *D. melanogaster* females heterozygous for an X chromosome inversion which transposes the nucleolus organiser to the tip of the X (refs 5, 6). It was proposed that these unintegrated ribosomal genes ($\sim 3 \times 10^8$ daltons) might be involved in position effect variegation⁵. This study was initiated to determine if a correlation exists between the presence of unintegrated ribosomal genes and the extent of position effect variegation in general. DNA from inversion-bearing male genotypes undergoing position-effect variegation was examined by sucrose gradient sedimentation and DNA-rRNA hybridisation. The resulting data further support a variegation association.

When the nucleolus organiser is moved by an inversion to the tip of the X chromosome, it has been shown to variegate⁷. Baker⁷ inferred from the lethality associated with *In(1)sc^L/0* and *In(1)sc^{S1}/0* males that these two X chromosome inversions were associated with a position effect suppression of ribosome synthesis. In the first series of experiments, the X chromosome

inversions used moved the nucleolus organiser to the tip of the X (*In(1)sc^{V2}*, *sc⁸*, *sc^{L8}*, and *sc^{S1}*). *In(1)sc^L*, on the other hand, has its proximal break distal to the nucleolus organiser and therefore left it at the base of the X. Oregon-R X chromosome was used as a wild-type control. DNA with a molecular weight of $\sim 5 \times 10^9$ was isolated from diploid brain and imaginal disks, and polytene salivary glands of third instar male larvae. Each male carried a specific X inversion and lacked a Y chromosome (*In(1)X/0*). As shown in Table 1, Oregon-R X/0 and *In(1)sc^L/0* males have no low molecular weight ribosomal genes in diploid tissue. rRNA hybridisation was within the high molecular weight DNA peak. Diploid larval tissue was analysed because of the lethality associated with some of the *In(1)X/0* genotypes⁷. The pattern of ribosomal gene integration found for adult flies has always been identical to that of the larval diploid tissue^{8,9}. All male genotypes which carry an inverted X with the right breakpoint between the nucleolus organiser and the centromere (*In(1)sc^{V2}*, *sc⁸*, *sc^{L8}*, and *sc^{S1}*) (Table 1) exhibit unintegrated ribosomal genes ($\sim 3 \times 10^8$ daltons) in increasing amounts. Of particular interest is the fact that *In(1)sc^{L8}/0* and *In(1)sc^{S1}/0* males produce the highest percentage of unintegrated ribosomal genes in diploid tissue and they also suffer the greatest lethality, since few males were observed to survive to third larval instar.

When the DNA from the polytene salivary glands was examined, all male genotypes had approximately 42% unintegrated ribosomal genes (Table 1). This percentage of low molecular weight genes in the salivary glands never varies, regardless of the genotype, and the finding has been discussed previously^{5,8}.

Mechanisms operating at the chromosomal level to affect gene expression may also be enhanced or suppressed by using suppressors of position-effect variegation³. One such locus is suppressor of variegation (*Su(var)*) in *D. melanogaster*. *Su(var)* is not a general modifier of position effect, it is limited to rearrangements involving specific heterochromatic regions (for example, *In(1)w^{m4}* and *rst³* compared with *In(1)sc^L*) (refs 10-13). In the second series of experiments, high molecular weight DNA was isolated from those inversion-bearing adult male genotypes which are affected by the *Su(var)* locus. The studies reported here were conducted using two alleles, *Su(var)* and *Su(var)⁺*, which can be maintained in homozygous stocks. *Su(var)⁺* enhances the variegation associated with *In(1)w^{m4}* and *In(1)rst³*, whereas *Su(var)* enhances variegation in *In(1)sc^L* (refs 3, 12, 14). When these suppressor alleles were associated with X chromosome inversions which enhance variegation, unintegrated ribosomal genes were present in all of the adult male genotypes analysed (Table 2). When variegation was suppressed by using *Su(var)* in association with *In(1)w^{m4}* and *In(1)rst³* and *Su(var)⁺* with *In(1)sc^L* (refs 3, 12, 14), no unintegrated ribosomal genes were found (Table 2).

Table 1 Percentage of unintegrated rDNA in male *D. melanogaster* of different genotypes

Genotype	Diploid brain and imaginal disks	Polytene salivary glands	No. of gradients analysed for each tissue
Ore-R X/0	0	42.1	3
<i>In(1)sc^L/0</i>	0	41.9	3
<i>In(1)sc^{V2}/0</i>	5.2	41.1	3
<i>In(1)sc⁸/0</i>	9.6	42.3	3
<i>In(1)sc^{L8}/0</i>	39.1	42.6	3
<i>In(1)sc^{S1}/0</i>	46.2	41.7	3

Drosophila melanogaster were labelled by growth at 23-25 °C on a low yeast medium as described previously^{8,9}. The medium contained 5 μ Ci ml⁻¹ ¹⁴C-methyl thymidine (50-60 mCi mmol, New England Nuclear). DNA isolation, sedimentation, and hybridisation of ³H-rRNA to the gradient fractions were as before^{8,9}. The *Drosophila* tissue culture rRNA used for the hybridisation had a specific activity of 309,000 c.p.m. μ g⁻¹. The stocks and inversions used in this study have been described previously^{5,8}. For genetic symbols and descriptions, refer to Lindsley and Grell¹⁰.

Table 2 Percentage of unintegrated rDNA in progeny adult males from female *D. melanogaster* of differing phenotype following inversion

Inversion	Mother	Progeny adult males	rDNA Unintegrated (%)
w^{m1}	Su(var) ⁺ /Su(var) ⁺	Su(var) ⁺ /Su(var) ⁺	17.8
w^{m1}	Su(var)/Su(var)	Su(var)/Su(var)	0
rst^2	Su(var) ⁺ /Su(var) ⁺	Su(var) ⁺ /Su(var) ⁺	16.2
rst^2	Su(var)/Su(var)	Su(var)/Su(var)	0
sc^1	Su(var)/Su(var)	Su(var)/Su(var)	18.2
sc^1	Su(var) ⁺ /Su(var) ⁺	Su(var) ⁺ /Su(var) ⁺	0

The *Drosophila* stocks and X chromosome inversions used have been described previously^{5,11-14}. The construction of genotypes was essentially the method of Spofford¹¹⁻¹⁴. Each inversion was placed opposite an attached X chromosome carrying the markers *y* (yellow) and *w* (white) and then introduced into companion stocks. The companion stocks were homozygous for *Su(var)* or for the *Su(var)*⁺ allele. This was done by a series of three crosses to replace the third chromosome of the inversion stock with *Ly Sb* (*Lyra*, *Stubble*) chromosome and then replace the latter with the *Su(var)* or *Su(var)*⁺ chromosome from coisogenic stocks. (The stocks carrying *Su(var)* or *Su(var)*⁺ were a gift of W. K. Baker, Chicago.) *Su(var)* and *Su(var)*⁺ females used for the crosses were tested for the *Su(var)* locus genotype by mating to *Dp(1:3)w^{m26.1-28.3}* males¹⁰⁻¹². For all the inversions studied, crosses between *Su(var)⁺/Su(var)⁺* or *Su(var)/Su(var)* were set up on ¹⁴C-methyl thymidine-labelled food. Adult sons carrying *Su(var)* or *Su(var)*⁺ and the inversion *In(1)w^{m1}*, *rst²*, or *sc¹* were picked from the progeny of each mating pair and their DNA was subjected to sucrose gradient sedimentation and hybridization to ³H-*Drosophila* rRNA. Three gradients were analysed for each inversion.

It seems that there is a diverse type of regulation of nucleolus organiser activity in *D. melanogaster*. This regulation can be expressed genetically as a variegated suppression of nucleolus organiser activity, or expressed physically in the form of unintegrated ribosomal genes. It is known that the physical structure of ribosomal DNA not only differs from the bulk of the DNA (ref. 15) but it also differs within the ribosomal DNA itself depending on the genotype^{5,6,8,9}. In *D. melanogaster* the nucleolus organiser, together with an undetermined extent of heterochromatin to either side of it, can also induce variegation in its neighbours when placed into euchromatin, for example near *et*, *l2*, or *in* (ref. 16). Inversions such as *In(1)sc^{V2}*, *sc^B*, *sc^{L8}* and *sc^{S1}* move a large amount of heterochromatin to the tip of the X chromosome, a condition which could favour variegation. Interestingly, Baker⁷ reported a decreasing viability index caused by suppression of the nucleolus organiser for *In(1)X/0* male genotypes (*sc^{L8}/0*:95; *sc^{V2}/0*:38; *sc^B/0*:14 or <1; and *sc^{S1}/0*:<1). In this study, I have found an increasing amount of unintegrated ribosomal genes as the apparent male viability decreased compared with female survival, and as the position effect increased. The viability of *In(1)sc^{L8}/0* and *In(1)sc^{S1}/0* males is partially restored by Y chromosomes with an altered nucleolus organiser and fully restored by unaltered Y chromosomes⁷. When these inversions were analysed in the presence of a Y, no unintegrated ribosomal genes were found^{5,6}.

In(1)sc^{S1}/0 male larvae were reported to have a 15% reduction in the amount of 18S and 28S rRNA (refs 17, 18). It was suggested that this reduction results from a suppression of transcription: perhaps it is the unintegrated ribosomal genes which cannot be transcribed efficiently. Furthermore, it has been suggested that the *Su(var)* locus might also affect a signal to begin message transcription¹⁴. It is not apparent, however, why the *Su(var)* locus should affect the nucleolus organiser region. The purpose of unintegrated ribosomal genes is still not understood. These genes have been postulated to be a result of chromosome pairing in inversion-bearing heterozygous females⁶. They have never been observed in adult males or in diploid tissue from male genotypes. The data presented here are the first to show that unintegrated ribosomal genes can occur in male genotypes of *D. melanogaster*. This report has also

presented two experimental situations in which position-effect variegation affects particular X chromosome inversions and also results in the presence of low molecular weight ribosomal genes. Little is known of the mechanism of position-effect variegation, but by studying chromosome rearrangements and factors which influence gene expression, a molecular explanation for the role of unintegrated genes in the variegation process may be found.

I thank Drs A. Gayler Harford and Thomas G. Sanders for reading the manuscript and for their helpful comments.

Evidence for a 'mammalian' thyroglobulin in endostyle of the ascidian *Styela clava*

ATTENTION has focused on the protochordate endostyle since the demonstration that certain of its cells could bind iodine¹⁻⁴. That has been confirmed by ultrastructural studies⁴⁻⁸, while the presence of thyroid hormones and their precursors has been established in endostylar extracts⁸⁻¹⁰. These findings have been questioned because the blood¹¹ and tunic^{12,13} can bind large amounts of iodine. Moreover, both iodotyrosines and iodothyronines can be isolated from tunic extracts¹²⁻¹⁵. Barrington has suggested that iodine-binding by the tunic is an invertebrate process associated with the extracellular iodination of inert structural scleroproteins, whereas endostylar iodination involves intracellular glycoproteins⁸. Using indirect immunofluorescence¹⁶, with rabbit anti-thyroglobulin serum, I have now identified a

Fig. 1 Photomicrograph of zones 7 and 8 from the endostyle of *S. clava*. Note the brilliant apical fluorescence in the ciliated zone 8. The fluorescence at the tips of zone 7 cells rather less distinct. Zeiss epi-fluorescence, mercury vapour lamp, blue excitation ($\times 300$).

protein in the endostyle of the ascidian *Styela clava* that is immunologically identical to mammalian thyroglobulin.

Figure 1 shows the specific localisation of thyroglobulin in zones 7 and 8 of the endostyle of *S. clava*. The distinctly brighter fluorescence in zone 8 may reflect fundamental differences in the quantity and/or quality of the intracellular material. Equally it may simply be due to secretory material trapped at the bases of cilia. Routine controls using saline or non-immune serum proved negative.

Thus, in the regions of the endostyle that are known actively to bind iodine intracellularly, the protein to which it is evidently bound is immunologically indistinguishable from mammalian thyroglobulin. Unquestionably protochordates must be regarded as very specialised animals¹⁷, and the extent to which the iodine-binding cells themselves have also become specialised is difficult to ascertain.

Notwithstanding such difficulties, this latest evidence for a thyroglobulin-like glycoprotein in the iodine-binding cells, together with the earlier work cited here clearly makes the concept of the endostylar origin of vertebrate thyroidal cells more credible.

Hormonal influences on ocular refraction in the rat

We report here that thyrotrophin (TSH) has a marked influence on ocular refraction in rats. In the clinical experience of one of us (C.C.K.-V.A.), adolescent myopia is not infrequently accompanied by increased height, suggesting a common, possibly hormonal, cause for both phenomena. No data on possible hormonal influences on eye growth or refraction could be found in the literature, but early anatomical studies showed that, during puberty, a growth spurt occurs in the eye after an early post-natal rapid weight increase¹⁻⁴. In a very detailed study, Weiss⁵ found relatively less growth of the sagittal eye axis as compared with the vertical and frontal diameters. Non-uniform growth rates along different eye axes might affect refraction.

In an attempt to assess hypophyseal influences on the eye, we studied the effects of some pituitary hormones on refraction and eye growth in rats. Seven-week-old ('adolescent') male Wistar rats were hypophysectomised and treated with a pituitary TSH preparation (Ambinon, Organon), which was dissolved in saline and injected subcutaneously twice daily, starting on the day after hypophysectomy. From preliminary experiments, a treatment period of 3 weeks was found to be optimal and was subsequently used unless indicated otherwise. Control rats were injected with saline alone. Ocular refraction was measured to the nearest dioptre by direct ophthalmoscopy after accommodation had been paralysed by a drop of 1%

Fig. 1 Irreversibility of TSH effects on ocular refraction in hypophysectomised rats. Hypophysectomy was on day 1 and injections from day 2, twice daily 0.1 ml subcutaneously. Controls received saline from day 2 to day 42 ($n = 9$). TSH + saline: 2 IU TSH d^{-1} from day 2 to day 21, saline from day 22 to day 42 ($n = 9$). Saline + TSH: saline from day 2 to day 21, 2 IU TSH d^{-1} from day 22 to day 42 ($n = 8$). Autopsy was carried out on day 42. Averages of refraction in both eyes per rat were used for computation. Columns represent means \pm s.e.m. * $P < 0.01$, compared with intact controls, computed by analysis of variance.

atropine solution, 1 h before examination. The animal was restrained manually and the entrance of the superior temporal vein in the ocular fundus was brought into focus by interposing the appropriate ophthalmoscope lens. In Tables 1 and 2, 'refraction' refers to the strength of this compensating lens, expressed in dioptres. It should be stressed that the high positive values of the 'refraction' do not mean that rats have a physiological hypermetropia, as it is known that small-eyed animals tend to exhibit large hypermetropia^{6,8} attributable to a measurement artefact arising from the ophthalmoscopic reflection occurring in front of the receptors⁹. The eyes of most animals are, in fact, thought to be emmetropic. The term 'hypermetropia' is used here, however, for the sake of brevity. Ophthalmoscopy was always carried out by the same investigator, using an eye that could not accommodate. In the experiment of Table 1, the ophthalmoscopist did not know to which group an animal belonged. An unbiased adherence to such a 'blind' procedure was not always possible in other experiments, as operation scars, growth retardation and behavioural changes were unavoidable clues as to an animal's treatment. (In frequent 'blind' checks, however, the reproducibility of measurements was ascertained.) Refraction changes due to stress-induced accommodation, such as occurs in teleosts⁷, could be excluded since the rats were cycloplegic after atropinisation. One day after the last ophthalmoscopic examination, the animals were killed with chloroform. The eyes were enucleated and weighed on a torsion balance; the lenses were then extracted and also weighed.

The results in Table 1 show that TSH brings about a dose-dependent change in refraction. No significant changes in eye or lens weights were evident.

In order to assess whether endogenous TSH has comparable effects, its production was enhanced by thyroidectomy on 7-week-old rats in a subsequent experiment. As is shown in Table 2, 3 weeks later, refraction had changed markedly compared with intact controls, although eye and lens weights were unchanged. In contrast, control animals which had only been hypophysectomised, had markedly lower eye and lens weights, but their refraction remained normal. The results of this experiment were taken as evidence for a direct effect of TSH on the eye, also occurring in the absence of the thyroid gland.

We then investigated whether the ocular effect of TSH is reversible. One group of rats hypophysectomised at 7

Table 1 Effect of exogenous thyrotrophin on ocular refraction and eye weight in hypophysectomised rats

Treatment	n	Body weight (g)		Refraction (D)				Weight total 2 eyes (mg)	Weight total 2 lenses (mg)
		Day 1	Day 21	Day 1		Day 21			
				L	R	L	R		
Saline	11	201	190	8±0.6	8±0.8	8±0.6	8±0.5	216±6	62±3.8
TSH 1 IU d ⁻¹	11	200	202	8±0.8	8±0.8	5±0.7*	5±0.5*	221±7	62±4.7
TSH 2 IU d ⁻¹	11	199	210	8±0.3	8±0.0	4±0.8†	4±0.6†	222±6	64±4.7

In all experiments, rats were exactly 7-weeks-old on day 1, when hypophysectomy was performed. Injections of TSH or saline (0.1 ml subcutaneously twice daily) were made from day 2 until killing on day 21. D: Refraction (in dioptres) measured by ophthalmoscopy. Analysis of variance:

* Statistically significant, $P < 0.01$, from control values and from TSH 2 IU d⁻¹.

† $P < 0.01$, from control values and from TSH 1 IU d⁻¹. Means ± standard deviation.

weeks of age was treated with 2 IU TSH daily for 3 weeks and subsequently with saline for 3 weeks. In a second group, a crossover design was followed, whereby the animals received saline for 3 weeks, followed by 2 IU TSH d⁻¹ for 3 weeks. Hypophysectomised controls received saline for 6 weeks. At the end of the experiment, both groups treated with TSH showed the same change in refraction as seen before (Fig. 1). The animals treated first with TSH, then with saline, showed the expected refraction

were treated with either 2 IU TSH d⁻¹, or ACTH (1 U per 100 g body weight subcutaneously every alternate day), or a combination of the two hormones in the same dosages; controls received saline. Treatment lasted for 3 weeks and the results are shown in Fig. 2. TSH decreased hypermetropia; ACTH when given alone had no effect. When the two hormones were given simultaneously, however, the effect of TSH was not only blocked but even reversed, resulting in increased hypermetropia.

Table 2 Effect of exogenous thyrotrophin on ocular refraction and eye weight in hypophysectomised rats

Treatment	n	Body weight (g)		Refraction (D)				Weight total 2 eyes (mg)	Weight total 2 lenses (mg)
		Day 1	Day 21	Day 1		Day 21			
				L	R	L	R		
Intact	10	190	309	8±0.7	8±0.3	8±0.4	8±0.4	226±7	62 ±2.3
Hypophysectomised	13	189	173	8±0.9	8±1.0	8±0.4	8±0.5	212±7*	58 ±3.4*
Thyroidectomised	10	190	251	8±0.5	8±0.8	5±0.5*	5±0.5*	227±6	59 ±6.7

Either hypophysectomy or thyroidectomy was performed on days 1 and 2. Animals were left untreated until killing on day 21. Analysis of variance: * Statistically significant, $P < 0.01$, from control values.

alteration, indicating that these effects persist for at least 3 weeks after discontinuation of TSH treatment.

From Table 2 it follows that in intact animals, in spite of the presumably continuous presence of TSH, no decrease in hypermetropia occurs between 7 and 10 weeks of age. Obviously, in such rats, compensatory influences are operative. In a first analysis of such a compensation by other pituitary hormones, 7-week-old hypophysectomised rats

In rats, the Harderian gland is the major retrobulbar constituent of orbital contents, having about the same weight as the eye⁸. Changes in gland size might cause deformation of the eye bulb and hence refraction changes. Therefore we looked for parallelism between changes in Harderian gland size and refraction under the influence of exogenous or endogenous TSH. Three weeks after hypophysectomy there was a marked atrophy of the Harderian gland, but refraction remained normal (Fig. 3). After TSH treatment of hypophysectomised animals, the decrease in hypermetropia was not accompanied by a change in gland atrophy. The rise of endogenous TSH after thyroidectomy, however, does not affect Harderian gland size, it only changes refraction. We therefore conclude that there is no causal relationship between Harderian gland size and refraction.

In conclusion, TSH induces changes in refraction of the rat eye by a process involving neither thyroid hormone nor the Harderian gland. Experiments to elucidate the physical, morphological and biochemical mechanisms causing refraction changes are in progress, with special attention being paid to corneal radius and refraction, and lenticular refraction and biochemistry.

No literature data have come to our knowledge on modifications of ocular refraction in the rat. As to eye growth in the rat, it is known that after very rapid growth in early life, the weight increases at a slower rate during the remaining lifespan⁹⁻¹¹. Although some factors such as food, care and physical condition have been shown to influence relative and absolute eye weight⁹, no specific hormonal factors have until now been held responsible for such phenomena. If TSH can be shown to affect refraction in man in a similar way to that in the rat, the data presented here open up

Fig. 2 Blockade by ACTH of TSH effect on ocular refraction in hypophysectomised rats. Hypophysectomy was on day 1. TSH (2 IU d⁻¹) and saline were injected twice daily. ACTH (1 IU per 100 g body weight) was injected every other day. No significant differences in eye weights were found. * $P < 0.01$, compared with saline-treated controls, computed by analysis of variance. Six animals in each group. Open columns, day 1; hatched columns, day 21.

Fig. 3 Effect of exogenous and endogenous TSH on Harderian glands and refraction in rats. Hypophysectomy (hypox.) or thyroidectomy (thyrect.) was performed on day 1. TSH treatment (2 IU d⁻¹) was given from day 2 until killing on day 21. Left column of each pair: refraction data as determined shortly before autopsy; right column: mg Harderian gland per 100 g body weight. **P* < 0.05; ***P* < 0.01.

interesting perspectives for pharmacological treatment of juvenile refraction aberrations.

Three forms of delayed skin-test response evoked by mycobacteria

Koch¹ first reported that when guinea-pigs which had been infected 4–6 weeks previously with tuberculosis were challenged intracutaneously (i.c.) with a small number of virulent organisms, there was induration and necrosis within 48 h, and localisation of the challenge dose. This phenomenon (classical tuberculin-type hypersensitivity) has often been regarded as a direct correlate of protective

immunity. But, the same challenge dose was not localised if injected intramuscularly (i.m.). This raised the possibility that 'protection' from the i.c. challenge was a trivial consequence of necrosis and sloughing of the infected skin. The controversy was highlighted by Wilson² who noted that pre-immunised guinea pigs showing an exquisite degree of hypersensitivity at the time of a small i.m. challenge with virulent *Mycobacterium tuberculosis* died more than 40 d before unimmunised controls, whereas weakly hypersensitive animals showed protection. We describe here a form of delayed foot-pad response which is evoked by all the non-pathogenic mycobacteria studied, but differs from the Koch-type response in timing and suppressor cell activity. It is not seen following injection of pathogens, and it is suggested that failure to evoke this response may account for their pathogenicity.

The existence of delayed hypersensitivity responses to mycobacteria, differing from the day 28 'Koch-type' was revealed by skin testing at intervals after injecting 10⁸ mycobacteria (see Fig. 1 legend) into groups of 20 or 40 BALB/c mice of either sex. Foot-pads were measured before and 24 h after challenge with 5 µg (protein) in 20 µl of saline of a 0.22-µm membrane filtered ultrasonic³ of the same organisms. Delayed hypersensitivity was calculated as per cent swelling in groups of 5–10 mice. All of eight species (provided by Dr J. L. Stanford) known to be non-pathogenic for the mouse (unpublished observation) gave curves of the type shown for *M. nonchromogenicum* in Fig. 1, with a pronounced peak at day 10. The mouse pathogens *M. ulcerans*, *M. kansasii*, and some *M. avium* strains gave a smaller peak between days 5 and 7, but the day 10–11 peak was absent. Similarly, relatively mouse virulent⁴ BCG strains such as Pasteur gave this pathogen-type curve, whereas Glaxo BCG which is of low mouse virulence⁴ gave a powerful day 10 peak. All the organisms gave rise to a later response which resembled the classical Koch type in that the peak occurred between 4 and 6 weeks.

None of the three peaks occurred in T lymphocyte-deprived mice injected with 10⁸ *M. nonchromogenicum* or BCG Pasteur. The day 10 response was readily transferred to normal recipients by the intravenous injection 2 × 10⁷ cells from nodes draining the injection site. This transfer was completely abrogated by killing the donor T cells with anti-Thy 1.2, and complement.

Treatment of the mice with intraperitoneal cyclophosphamide, 200 mg per kg body weight 24 h before injection of the bacilli increased the day 6–7 response, without affecting the day 10 peak, if present, or the subsequent day 17 trough. This observation suggested that the day 6–7 peak represented the 'Jones-Mote' phenomenon which typically occurs at 7 d, and is known to be induced by most, if not all mycobacterial species⁵. A regulator of this phenomenon has been reported to be a cyclophosphamide sensitive lymphocyte, in both the guinea pig⁶ and the mouse⁷.

The nature of the 'trough' occurring 17 d after subcutaneous (s.c.) injections of non-pathogenic species (Fig. 1) was investigated by transferring 0.5 ml of fresh serum, or 1.5 × 10⁷ cells from nodes draining the injection site of such day 17 animals, into recipients at other points on the time course (Table 1). Thus normal animals, or mice which had received organisms s.c. 6, 10 or 28 d earlier, received day 17 cells, or serum, or both 1 h before being foot-pad tested.

Neither day 17 cells, nor day 17 serum had demonstrable effects on the foot pad-test responses of control, or day 6 (Jones-Mote) mice. But, day 17 cells suppressed both the day 10, and the day 28 peaks, particularly the latter. Recovery from this suppression was partial by 7 d but complete 14 d later (Table 1).

Day 17 serum enhanced the day 10 peak, but was without

Table 1 Delayed skin-test response to *M. nonchromogenicum*

Treatment of recipients	Controls	Foot-pad responses in recipients (% swelling at 24 h)			Day 28 retested 14 d later
		Day 6	Day 10	Day 28	
None	5.7±4.4	20.3±4.9	38.6 ± 6.2	35.9 ± 12.0	33.1 ± 13.0
1.5 × 10 ⁷ day 17 cells*	4.3±1.6	20.5±4.4	28.3† ± 4.1	9.1† ± 5.4	30.4 ± 7.5
0.5 ml day 17 serum*	5.6±4.4	28.3±7.2	66.9‡ ± 13.9	35.5 ± 11.2	ND
1.5 × 10 ⁷ cells and 0.5 ml serum*	ND	ND	ND	23.0 ± 8.4	ND

Effect of cells or serum taken from BALB/c mice 17 d after 10⁸ *M. nonchromogenicum* s.c., on the foot-pad responses to 5 µg of antigen, of normal mice, or mice which had received 10⁸ organisms s.c., 6, 10 or 28 d earlier. (10 mice in each group.) ND, not determined.

*Injected intravenously 1 h before the foot-pad test.

‡Significantly different from control group. ($P < 0.025$).

effect on the day 28 response. But, in subsequent experiments, when transferred into day 28 animals which also received day 17 cells, the serum partially reversed the suppressive effect of the cells, implying that when the serum factor enhanced it did so by opposing suppressor cells, rather than by a direct influence on effector cells. It will be important to find whether this serum factor is similar to that which accompanies tissue-damaging reversal reactions in human leprosy⁸.

Neither day 17 cells or serum had any significant effect on the delayed hypersensitivity responses to sheep red blood cells, or picryl chloride in appropriately immunised mice.

The major observation here, is that only pathogenic mycobacteria either do not evoke, or are able to suppress the day 10 type of T lymphocyte-dependent response. This is circumstantial evidence for a protective role for this response, which, in timing resembles delayed hypersensitivity evoked by other intracellular parasites such as *Listeria monocytogenes*⁹, and *Leishmania*¹⁰. Thus the mechanism of immunity to mycobacteria in the subclinically infected individual may not be the 4–6 week Koch type of hypersensitivity as has often been assumed^{2,11} but may be very similar to that involved in protection from other intracellular organisms. This day 10 peak is accompanied by, and eventually switched off by suppressor

or 'regulator' cells (day 17) the effects of which are modulated by a serum factor. The later day 28 response differs not only in timing, but also in that this type of suppressor cell seems to be absent. This 4–6 week 'Koch-type' of hypersensitivity might be due to a failure of the normal homeostatic suppressor cell mediated regulatory mechanisms. (An ability of mycobacteria to interfere with suppressor cell production would explain the efficiency with which mycobacterial adjuvants will induce auto-immune responses.)

The 4–6 week delay before the appearance of the 'Koch-type' hypersensitivity is explained by the observation that its development is a two stage process. The first stage, which is not antigen specific, requires 2–3 weeks of exposure of lymphoid tissue to mycobacterial components. Thus when sheep red cells (SRBC) were injected into sites previously primed with Pasteur BCG which gives a pathogen-type of curve and fails to evoke day 10 peak, maximal potentiation of the response was seen if the SRBC were injected 2 weeks after the BCG¹². No potentiation was seen if both injections were given at the same time. Similarly, dead mycobacteria, or killed organisms, which traditionally do not induce 'Koch-type' hypersensitivity, give powerful responses if injected twice into the same site with a 2-week interval (data not shown).

Live, virulent organisms do not need to be injected twice, because having escaped the day 10 response by suppressing or failing to evoke it, they continue to proliferate and release antigen which reaches the lymphoid tissue after the first stage of non-antigen specific 'conditioning'. The resulting unregulated, day 28 or 'Koch-type' tissue-destructive hypersensitivity was probably responsible for the accelerated death of Wilsons guinea pigs, and this would help to explain cavitating pulmonary tuberculosis and reversal reactions and nerve damage in tuberculoïd leprosy.

Influenza A viruses of the H2N2 subtype are lymphocyte mitogens

STUDIES of the effects of viral infections have largely been concerned with intracellular interactions between viral and cellular functions. There is increasing realisation that the cell surface has a major role in cellular function and various cell surface active substances, for example, concanavalin A (con A)¹ and phytohaemagglutinin (PHA)², exert profound effects on cellular metabolism. As the cell surface possesses receptors specific for various viruses and viral antigens, it might be expected that certain viruses could affect cellular function as a result of cell surface interaction. Proliferation is a characteristic response of lymphocytes exposed to these cell surface active compounds. This response can be readily quantitated using ³H-thymidine incorporation. We report here that influenza viruses of the H2N2 subtype are potent mitogens for both B and T lymphocytes³. This finding arose during studies aimed at developing assays for cell-mediated immunity to influenza virus infection⁴⁻⁷. We observed that spleen cells from normal mice showed increased levels of ³H-thymidine incorporation when exposed *in vitro* to the A/Singapore/1/57 virus. This model system should provide insight to questions of lymphocyte triggering and bring attention to this aspect of cell-virus interaction.

As illustrated in Fig. 1, maximum stimulation of normal mouse splenic lymphocytes occurred 48 h after the addition of 10 μ l of A/Singapore virus from a stock containing 10^{7.3} 50% egg infectious dose (EID₅₀) per 0.1 ml. Experiments were designed to determine whether the mitogenic activity of the egg grown stock was virus-associated and, if so, whether it was dependent on virus infectivity. A/Singapore virus was therefore sedimented in an ultracentrifuge and the supernatant and viral pellet were separated. Mitogenic activity was associated with the viral pellet (stimulation ratio (SR) of 3.9) but not with the supernatant fluid (SR of 0.9). In addition, the A/Singapore virus stock was shown to be free from bacterial contamination and had no detectable endotoxin (lipopolysaccharide), a known B cell mitogen, when assayed by the limulus lysate test (sensitivity < 0.5 ng ml⁻¹). Experiments were performed with live (10^{7.3} EID₅₀ per 0.1 ml) and ultraviolet-inactivated (< 10^{6.5} EID₅₀ per 0.1 ml) virus. These experiments indicated that virus infectivity was not required for stimulation, the SR of live and inactivated virus being 11.6 and 18.3 respectively.

The nature of the cells responding to A/Singapore virus was then evaluated. The response of untreated spleen cells was compared with that of either spleen cells depleted of T cells by treatment with anti- θ serum plus complement or

Fig. 1 Effect of time of incubation and dose of A/Singapore virus on *in vitro* proliferation of normal BALB/c splenic lymphocytes. ▲, 0.1 μ l; ●, 10 μ l; △, 30 μ l; and ■, 60 μ l of the A/Singapore virus; ○, 5 μ g con A. In these experiments normal spleens were removed from various animals and single cell suspensions were prepared. Erythrocytes were lysed by exposure of the spleen cells to buffered ammonium chloride solution⁸. Lymphocytes were resuspended to a concentration of 3×10^6 viable cells per ml in RPMI 1640 containing 4% heat-inactivated foetal bovine serum and 2×10^{-4} M 2-mercaptoethanol. Volumes of 0.2 ml of lymphocyte suspension were added to wells of microtitre plates (Microtest II, Falcon). A/Singapore virus was added in varying volumes to quadruplicate samples of normal lymphocytes. These studies were performed using an egg-passaged pool of A/Singapore virus with an egg-infectivity titre of 10^{7.3} EID₅₀ per 0.1 ml. The microtitre plates were incubated for 44 h at 37 °C in a 5% CO₂-95% air atmosphere. At this time 1 μ Ci of ³H-thymidine (specific activity, 6 Ci mmol⁻¹) (Schwarz/Mann) was added per well. After 4 h of further incubation, the cells were collected on to glass fibre filter strips using a MASH II harvester (Microbiological Associates) and the incorporation of ³H-thymidine determined by scintillation counting. Mean incorporation was determined for each group and a stimulation ratio (SR) derived by dividing the mean c.p.m. incorporated in the presence of virus by the mean c.p.m. incorporated in the absence of virus.

spleen cells depleted of B cells by passage through nylon fibre columns according to the method of Julius *et al.*¹⁰. As indicated in Table 1, both T- and B-enriched lymphocyte populations were stimulated by the A/Singapore virus. The responsiveness of B lymphocytes was confirmed in studies using splenic lymphocytes obtained from T-cell deficient nude (athymic) mice (Table 2).

Blastogenic responses were observed with lymphocytes from several mouse strains tested, including those from BALB/c mice raised in a germ-free environment. In addition, lymphocytes from human peripheral blood and spleen cells from Hartley guinea pigs and New Zealand white rabbits were stimulated by A/Singapore virus (Table 2).

Additional influenza viruses were tested for mitogenic activity. Splenic lymphocytes from normal BALB/c mice showed significantly increased levels of ³H-thymidine incorporation when exposed *in vitro* to all influenza viruses of the H2N2 subtype tested (Table 3). Influenza viruses of other subtypes produced little or no stimulation.

These studies indicate that several egg grown influenza viruses of the H2N2 subtype possess significant mitogenic activity for normal T and B lymphocytes. In addition, A/Japan/305 virus grown in a canine kidney cell line (MDCK) possessed mitogenic activity similar to that of the egg-grown virus. The observed blastogenesis is unlikely to be due to a specific immune response associated with cross-

Table 1 Mitogenic effect of A/Singapore influenza virus on T and B enriched lymphocyte populations

Treatment of normal BALB/c spleen cells	Mean stimulation ratio in cultures containing A/Singapore virus	
	A/Singapore virus	Con A
Untreated	6.2	2.7
Passed through nylon fibre column	4.4	16.7
Treated with complement	2.4	4.1
Treated with anti- θ plus complement	2.4	1.1

Quadruplicate cultures of treated and untreated spleen cells from BALB/c mice were incubated either in the presence or absence of A/Singapore virus as described in Fig. 1. A stimulation ratio for each of the four replicate cultures containing virus was calculated by dividing the counts of ³H-thymidine incorporated in each culture by the mean of the counts of ³H-thymidine incorporated in the quadruplicate cultures not containing virus (approximately 10⁴ c.p.m.). The value shown is the mean of the four calculated stimulation ratios. In all experimental groups, the range of the stimulation ratios observed in quadruplicate samples were within 10% of the mean value shown. Similar results were observed in repeat experiments.

Table 2 Mitogenic effect of A/Singapore influenza virus on normal lymphocytes

Source of lymphocytes tested for mitogenic activity	Mean stimulation ratio in the presence of A/Singapore virus
Nude mouse spleen	3.0
C3 H mouse spleen	10.2
Germfree mouse spleen	13.2
Human peripheral blood*	10.6
Guinea pig spleen	4.5
Rabbit spleen	3.2

The stimulation ratios shown are those calculated from four replicate lymphocyte cultures containing A/Singapore virus as described in Table 1. The mean counts of ^3H -thymidine incorporated in quadruplicate cultures not containing virus had a range between 10^3 and 10^4 c.p.m. In all experimental groups, the range of the stimulation ratios observed in quadruplicate samples were within 10% of the mean value shown. Similar results were observed in repeat experiments.

*Healthy adults aged 30–35 yr.

reacting microbial antigens because of the responsiveness of lymphocytes from germ-free mice. Nor is it likely to be due to virus infection of lymphocytes as ultraviolet-inactivated virus retained mitogenicity. Rather the data favour a cellular effect due to virus binding to the lymphoid cell surface. The H2N2 subtype has several distinguishing characteristics which separate those viruses from other influenza subtypes. The most notable feature and basis for classification of the subtype is the possession of the H2 haemagglutinin glycoprotein on the viral envelope. As all A type influenza viruses possess similar matrix and nucleoproteins and because viruses possessing the same neuraminidase (N2) but a different haemagglutinin (H3) did not stimulate lymphocytes (Table 3), these results suggest that the H2 glycoprotein is responsible for this mitogenic activity. Analyses of differences between H2N2 and other influenza viruses should give insight into the molecular basis of the cell surface interaction leading to lymphocyte transformation.

This report presents data that clearly demonstrate that H2N2 influenza viruses are mitogenic for lymphocytes. The possible effects of H2N2 influenza viruses on other types of cells remains to be determined. Another important question is whether other viruses exist with a mitogenic capacity

Table 3 Mitogenic effect of H2N2 influenza viruses on normal lymphocytes

Viruses tested for mitogenic activity		Mean stimulation ratio
A/Singapore/1/57	(H2N2)*	7.7
A/Japan/305/57	(H2N2)	8.9
A/Japan/170/62	(H2N2)	11.5
A/Taiwan/1/64	(H2N2)	10.7
A/Ann Arbor/7/67	(H2N2)	8.9
A/Tokyo/3/67	(H2N2)	6.4
A/Cornell/1001/67	(H2N2)	9.4

A/Victoria/3/75	(H3N2)	0.6

Quadruplicate cultures of spleen cells from BALB/c mice were incubated in the presence of several influenza A virus subtypes as described in Fig. 1. A mean stimulation ratio for each of the four replicate cultures containing virus was calculated as described in Table 1. The mean counts of ^3H -thymidine incorporated in quadruplicate cultures not containing virus was 2×10^4 c.p.m. In all experimental groups, the range of the stimulation ratios observed in quadruplicate samples were within 10% of the mean value shown. Similar results were observed in repeat experiments.

*Major surface antigens: haemagglutinin (H), neuraminidase (N).

similar to H2N2 influenza viruses. Finally the biological relevance of virus-stimulated proliferative lymphocyte responses needs to be clarified. Compared to resting lymphocytes, mitogen-activated lymphocytes are more permissive for growth of a wide variety of RNA and DNA viruses^{11–13}. In addition mitogen-induced proliferation has been shown to cause the activation of endogenous xenotropic type-C RNA virus from murine spleen cells^{14–15}. The possible contribution to disease pathogenesis due to mitogenic activity of viruses clearly deserves more study.

Antibody to nuclear ribonucleoprotein penetrates live human mononuclear cells through Fc receptors

It is commonly accepted that antibodies do not penetrate living cells. In only one study anti-purine and anti-nucleoside antibodies were found to penetrate fertilised sea urchin eggs and modify their development¹. Such penetration has been considered unusual and the addition of anti-DNA antibodies does not affect mammalian tissue cells in culture². Direct immunofluorescence of skin biopsies of patients with mixed connective tissue disease (MCTD) using fluorescent anti-IgG has occasionally shown speckled intranuclear fluorescence^{3–5} but it is doubted that IgG entered the cells while still viable. Patients with MCTD have high titres of antibody to nuclear ribonucleoprotein (RNP)^{6,7} which also gives a nuclear speckled pattern on cell substrates in direct immunofluorescence⁸. Should the antibodies to cellular components and nucleic acids which occur in autoimmune diseases be able to penetrate living cells, a novel mechanism of immunologically mediated damage and/or dysfunction could operate. We show here that anti-RNP IgG can penetrate viable human mononuclear cells (MNC), by their surface Fc receptor, and react with their nuclear RNP.

To study the possible penetration of antibodies into viable cells we used an anti-RNP antibody present at high titres (1:16,384,000), as detected by a haemagglutination assay⁷, in the serum of a patient who fulfilled our criteria for MCTD⁹. This serum was unreactive with ribonuclease-treated extractable nuclear antigen (ENA), gave a single precipitin line on Ouchterlony analysis against untreated ENA, indicating its sole reactivity with RNP, and gave the characteristic speckled pattern on indirect immunofluorescence using frozen section of rat stomach as a cell substrate (Fig. 1a). It contained $106,680 \text{ mg l}^{-1}$ of IgG, 2,680 of

Fig. 1a. Nuclear speckled pattern under epifluorescent microscopy of a frozen section of rat stomach stained with the fluorescein-labelled anti-RNP IgG antibody. The sections were incubated for 25 min with the antiserum, washed for 20 min with isotonic saline under constant agitation, mounted with 0.1 M Glycine buffer, pH 8.6 with 2 parts glycerol, and read. *b*, Speckled nuclear pattern of a viable MNC after incubation with fluorescein-labelled anti-RNP IgG antibody. Viability was controlled by Trypan blue exclusion. *c*, Two viable MNC under fluorescent microscope after incubation with the fluorescent anti-RNP antibody. The lower one shows intranuclear fluorescence as well as three dots of cytoplasmic fluorescence. The upper one shows membrane fluorescence. *d*, A viable MNC, probably a macrophage, shows lumps of intracytoplasmic fluorescence after having been incubated with the fluorescent anti-RNP antibody. All photographs were taken with a C35 47 6070 Zeiss microscope camera using tri-X-pan Kodak film at original magnification of 800 \times .

IgA, and 2,520 of IgM as determined by radial immunodiffusion in commercial antibody-agar plates (Behringwerke). The IgG anti-RNP antibody-containing fractions obtained in Sephadex G-200 column fractionation had a titre of anti-RNP antibody of 1:1,048,576 at a protein concentration of 42 mg ml⁻¹. This IgG was tagged to fluorescent isothiocyanate by conventional methods and was absorbed with rat liver powder to eliminate unspecific fluorescence. To avoid the lymphocytotoxic activity found in MCTD sera¹⁰ we also absorbed it repeatedly with human brain cortex, which is known to share antigenic determinants with lymphocytes¹². The brain cortex was previously treated with ribonuclease-A (Sigma, lot 115C-0008) in order to avoid absorption of the anti-RNP antibody by RNP present in this tissue. Following this treatment, the mean lymphocytotoxic activity in a panel from 10 normal human donors in a modification of the microcytotoxicity assay of Terasaki and McClelland^{10,11} was 15%, which is close to that of normal sera¹¹, while the anti-RNP antibody titre remained unchanged. Viability of human peripheral blood mononuclear cells (MNC), obtained from normal donors by the Ficoll-Hypaque method of Böyum¹¹, was tested by Trypan blue exclusion after incubation with the antibody and was found to be 84.6%, which was acceptable for our studies. All subsequent studies were done using this absorbed, fluorescent anti-RNP IgG, and were controlled for viability by Trypan blue exclusion.

One fifth of all viable MNC from five normal subjects showed intranuclear fluorescence (Table 1) with the characteristic speckled pattern of anti-RNP when incubated 60 min at 37°C with the fluorescent antibody (Fig. 1b). Longer incubation did not increase the number of viable cells with intranuclear speckled fluorescence. Membrane fluorescence (Fig. 1c) was found in 17% of viable cells but seldom concurred with intranuclear fluorescence (Table 1). Capping was seen occasionally. Intracytoplasmic fluorescence seen in 6% of cells (Fig. 1d), was seldom associated with intranuclear fluorescence.

To determine if membrane and cytoplasmic fluorescence could represent steps in the pathway to the nucleus of the anti-RNP antibody, sequential studies were done after increasing in-

cubation times (Table 1). Within 1 h there was a stepwise increase of cells bearing intranuclear fluorescence as well as of those with membrane fluorescence. Inasmuch as fluorescence in these two locations increased in a parallel fashion, it could not be interpreted as steps of the same process. The different proportions of cells bearing nuclear fluorescence, as compared to those bearing membrane fluorescence, when enriched subpopulations were studied (*vide infra*), also suggest that these two different locations of fluorescence occur in different cell subpopulations rather than being stages of antibody penetration. Conversely, cytoplasmic fluorescence decreased along with intranuclear fluorescence in experiments in which penetration of the antibody was blocked (Table 1), suggesting that cytoplasmic fluorescence is due to the antibody on its way to the nucleus.

Five per cent of those viable MNC which adhered to glass wool columns or Petri dishes and stained with myeloperoxidase, indicating them to be predominantly macrophages¹³, were found to have intranuclear staining after incubation with the antibody, while 14% of non-adherent viable MNC showed such intranuclear staining. It therefore seems that the MNC into which the antibody penetrates are primarily lymphocytes, although it may also enter macrophages. To find into which lymphocyte subpopulation the antibody penetrates we prepared cell suspensions enriched for either B or T lymphocytes by a double Ficoll-Hypaque gradient method¹⁴. Suspensions containing predominantly B lymphocytes showed considerably greater percentages of intranuclear staining than those containing predominantly T lymphocytes (Table 1).

The percentages of viable MNC showing intranuclear staining by the labelled anti-RNP antibody are similar to those of MNC bearing receptors for the Fc fragment of IgG¹⁵. To determine if the Fc receptor-bearing MNC are those into which the antibody enters, they were incubated with antibody-coated chicken erythrocytes¹⁶ and the fluorescent anti-RNP antibody simultaneously. Fluorescent staining of nuclei was practically limited to cells forming Fc rosettes.

As the question of viability is crucial in establishing the significance of these findings, and because both Trypan blue exclusion and rosette formation may not be reliable indicators of cell viability at a given moment, we cultured in a 5% CO₂ atmosphere normal MNC pre-incubated with the labelled antibody and shown to have it internalised. Presence of cells bearing speckled intranuclear fluorescence after 24 h of culture confirmed their viability when penetration of the antibody occurred.

Since the antibody penetrates primarily into Fc receptor-bearing cells, this receptor could have a role in the uptake and entrance of the antibody. Normal human MNC were incubated for 1 h with heat-aggregated normal human Cohn's fraction II¹⁷ at concentrations ranging from 16 to 260 μ g per 10⁶ cells before incubation with the labelled antibody (Table 1). Abrogation of antibody penetration by pre-incubation with aggregated γ -globulin was dose related (Table 1), which strongly suggested a blockade of Fc receptors interfering with antibody penetration. Pre-incubation of the MNC cells for 1 h with Fc fragments from human IgG at a concentration of 120 μ g per 10⁶ cells, obtained by papain cleavage of the anti-RNP IgG by a modification of the Porter's method¹⁸, resulted in an 80% decrease of intranuclear fluorescence. Fluorescein labelled F(ab')₂ fragments of the anti-RNP IgG prepared by pepsin digestion¹⁸ failed to penetrate into MNC although they remained capable of giving direct nuclear immunofluorescence in frozen sections of rat stomach.

Because of their large size, antibody coated chicken erythrocytes did not block all Fc receptors and allowed penetration of antibody in experiments combining fluorescent labelling and Fc rosette formation. The dose dependent blocking by aggregated IgG and by Fc fragments supports this explanation.

It is apparent that the anti-RNP IgG antibody penetrates viable human MNC via their Fc receptors and reaches the nucleus where its antigen resides. The significance of these findings may be manifold. (1) The potential for antibodies to penetrate living mammalian cells—this antibody cell penetration could have several implications in immunobiology: selective deletion of the

†MNC obtained in Ficoll-Hypaque gradient were adjusted to a concentration of 1×10^6 cells per 0.1 ml of minimum essential medium (Eagle) enriched with 0.8% L-glutamine (MEM) were placed in 0.1 ml aliquots and incubated at 37 °C in a 5% CO₂ and 100% humidity atmosphere. Cells were then washed in phosphate buffered saline pH 7.4 (PBS), resuspended in PBS, incubated 5 min with 0.1 ml of a 0.2% Trypan blue dye solution at room temperature, and counted immediately under epifluorescent (Zeiss: Filters UG 1/3, FT: 420, LP 418), and normal illumination. To determine the percentages of cells showing fluorescence at various sites we consider only those cells found to exclude the Trypan blue dye.

‡In this and all subsequent experiments, the incubation time of the MNC with the anti-RNP antibody or its fractions was 60 min.

§Glass wool obtained from J. T. Baker, Phillipsburgh, N. J., USA, Lot 39,284, was loosely packed into a Pasteur pipette filled with MEM and incubated at 37 °C for 30 min. MNC resuspended in the same medium were carefully layered on top of the glass wool and incubated 30 min. with the pipette in vertical position and the tip closed. The pipette tip was opened and 10 ml of MEM were passed through the pipette to collect non-adherent cells. The pipette was then broken and the glass wool washed in PBS, to obtain adherent cells.

antibodies, selective triggering of cell proliferation, a mechanism for memory storing, or, if such be the case, interaction with intracellular antigens. (2) A previously unsuspected role for the Fc receptor in the cellular penetration of antibodies. (3) By a peculiar tropism and/or attraction this antibody, once inside the cell, might make its way to the nucleus to interact with its antigen. And (4), a possible new mechanism of immunologically mediated damage might occur in diseases where antibodies to cell constituents, to nucleic acids and to nucleic acid-protein antigens appear and might modify function when entering a living cell. This mechanism would resemble that of stimulation (type V) as proposed in the Roitt's modification of the Gell and Coombs classification¹⁹.

We have found that intranuclear penetration by antibody occurs *in vivo* in human disease. Patients with MCTD have intranuclear immunoglobulin in their circulating MNC, detectable by means of indirect immunofluorescence using goat antibody to human immunoglobulins, which is thus, also capable of penetrating viable cells. Details of this finding will be reported elsewhere.

Carcinogen-induced chromosome breakage in Fanconi's anaemia heterozygous cells

FANCONI'S anaemia (FA) is one of the genetic syndromes in which chromosomal instability has been associated with an increased predisposition to cancer¹. An increased risk of malignancy has also been reported for presumptive carriers of the FA gene^{2,3}, although no evidence of chromosome abnormalities has been found in cultured lymphocytes or fibroblasts from the FA heterozygote. The nature of the genetic defect in FA is still unclear, although there is evidence for defective DNA repair⁴⁻⁶.

Table 1 DEB-induced chromosome breakage in Fanconi's anaemia heterozygous and normal cells

Cell strain	Passage no.	Chromatid breaks	Chromosome breaks	Fragments + deletions	Rearrangements*	No. of breaks per cell†
FA heterozygotes‡

Treated	12	5	0	0	1	0.07
C39						
Untreated	11	2	0	1	0	0.03
Treated	11	2	0	3	0	0.05

*Rearrangements include translocations, dicentric, and rings and are scored as two breaks.

†100 cells were analysed in each set.

‡FA heterozygous and normal cultures were not identified until after data were tabulated. C13, 31-yr-old male; father of FA patient C12, previously tested using this same *in vitro* system¹⁰; C59, 40-yr-old male; C57, 49-yr-old female; C40, 23-yr-old male; C39, 26-yr-old male.

Lymphocytes from FA homozygotes have an increased incidence of chromosome aberrations after exposure to ionising radiation⁷ or alkylating agents^{8,9}. We reported recently that baseline breakage rates for FA cell strains varied from 0.20 to 0.36 breaks per cell, and that after carcinogen treatment of the type described below, these rates were increased three to fivefold¹⁰. The same carcinogen treatment had no clastogenic effect on normal, xeroderma pigmentosum and trisomy 18 fibroblasts. There is at present no way to distinguish FA heterozygous individuals from normal. The only distinction that has been reported has been an increased susceptibility to *in vitro* transformation by the oncogenic virus SV40 in both homozygous and heterozygous FA fibroblasts¹¹, but similar results have been obtained with cell strains from patients with several other syndromes. As the ability to identify carriers of the FA gene would be of great benefit because of their increased cancer risk, we report here the results of experiments in which we were able to distinguish FA heterozygous cell strains from normals, after exposing the cells to the difunctional alkylating agent diepoxybutane (DEB), an active mutagen and carcinogen¹²⁻¹⁵.

Early passage skin fibroblasts from five individuals were obtained from Dr M. Swift (University of North Carolina at Chapel Hill). We received the flasks coded, and the identity of the strains was revealed only after results of the experiments were tabulated. Cells from each strain were exposed to 0.01 μ g of DEB per ml medium for 6 d, while replicate cultures served as untreated controls. At this concentration, DEB had no cytotoxicity in these strains; treated cells showed approximately the same growth curve as untreated.

The effect of DEB treatment on chromosome breakage in these cells is shown in Table 1. One hundred cells were analysed in each group. The approximately fivefold increase in breakage in the FA heterozygous cells after treatment with DEB was highly significant ($P < 0.001$). The breakage was not concentrated in a few cells, but fit a Poisson distribution. Qualitatively, the chromosomal aberrations induced by DEB in FA heterozygous cells were similar to those which occur spontaneously in FA homozygous cells; open chromatid breaks were the most common finding. In contrast to this result in the FA heterozygous cells, there was no increase in chromosome breakage in normal cells, even those with the highest intrinsic break rate (normal cell strain C40, see Table 1).

Our results indicate that the use of a clastogenic agent in an *in vitro* stress system may have value as a method for determining whether presumptive heterozygotes are in fact gene carriers for FA. In earlier studies exposure of FA heterozygous cells to alkylating agents did not induce increased chromosomal aber-

rations, or increased sister chromatid exchanges greater than that observed in normal cells^{5,8}. Those studies involved direct analysis of exposed lymphocytes. The fibroblast system used in this study may offer a more sensitive means of detecting susceptibility to induced chromosome breakage. Chronic exposure to a non-toxic concentration of the alkylating agent may produce a greater load of DNA damage in a cell population still capable of mitotic division. Perhaps FA heterozygous cells have a reduced capacity to repair DNA, which is not apparent except under the stress of increased damage. As in xeroderma pigmentosum cells^{16,17}, increased sensitivity to chemically-induced chromosome instability occurred in cells lacking spontaneous chromosome breakage.

Although individuals affected with FA are rare, the heterozygote frequency is estimated at 1 in 300 and FA heterozygotes could comprise 1% of all persons dying from cancer². The ability to identify FA heterozygotes would make possible a direct assessment of the risk for carriers of the FA gene acquiring cancer, as compared to the general population. It would also be possible to offer a screening programme for early detection of cancer to individuals identified as FA heterozygotes. The use of an *in vitro* system based on extended exposure to low levels of a carcinogen may provide an effective stress test for the detection of other genes which predispose to cancer.

We thank Drs J. Mitra and R. S. K. Chaganti for helpful discussions, Dr M. Swift for cell strains, and Dr B. M. Goldschmidt for providing the DEB. This study was supported in part by the Martha and Regina Brand Foundation.

Increased CTP synthetase activity in cancer cells

AN insight into the biochemical strategy of cancer cells has been achieved by the conceptual and experimental approach provided by the molecular correlation concept^{1,2}. Studies carried out using this approach with model systems of rat hepatomas and kidney tumours of different growth rates revealed a biochemical imbalance in cancer cells, which manifested itself in progressive changes in activities of key enzymes and overall metabolic pathways that correlated with tumour growth rate^{1,2}. Some of these biochemical alterations have been shown to apply to human primary liver³ and kidney⁴ carcinomas. Those alterations in gene expression that are linked to the increase in the expression of malignancy are manifested in the increased activities of key glycolytic-, purine-, pyrimidine-, DNA- and polyamine-synthesising enzymes¹⁻⁸. Concurrently, decreases occur in the activities of the key enzymes of gluconeogenesis, purine and pyrimidine catabolism and of the urea cycle^{1-5,9,10}. In addition to such a progression-linked (growth-rate-linked) metabolic imbalance, the reprogramming of gene expression in cancer cells entails transformation-linked alterations that are present in all hepatomas irrespective of growth rate or extent of differentiation^{1,2,11-15}. Here we report that CTP synthetase (UTP:L-glutamine amidoligase, EC 6.3.4.2) increased in all the hepatomas examined, the activity being highest in the rapidly growing tumours. Thus, in liver neoplasia the activity of this enzyme is both transformation- and progression-linked. CTP synthetase activity was also markedly increased in transplantable kidney tumours in the rat and in primary renal cell carcinomas in man.

Our studies on CTP synthetase, the enzyme that catalyses the synthesis of CTP from UTP, were undertaken because the activity of UDP kinase, an enzyme that produces UTP, was elevated in all hepatomas examined¹⁵. In rapidly growing hepatoma 3924A, however, the concentration of UTP was unaltered, but the CTP concentration was increased fivefold¹⁶. An accumulation of CTP might occur because of decreased utilisation, which is not likely in the rapidly growing tumour; or it might be caused by an increase in the activity of CTP synthetase, an enzyme that is a sensitive target for anti-tumour active glutamine antagonists¹⁷. We have tested the hypothesis that the observed increase in CTP concentration may be accounted for, at least in part, by an increase in CTP synthetase activity. Our systematic studies revealed that CTP synthetase is the rate-limiting enzyme in hepatic CTP biosynthesis (Fig. 1). The specific activity of CTP synthetase was increased in all hepatomas examined, and the elevation correlated with the increase in tumour growth rate. This increased potential for CTP biosynthesis provides one mechanism by which the cancer cell can adjust the availability of CTP for RNA synthesis and for the formation of 2'-deoxy CTP for the synthesis of DNA.

Male ACI/N and Buffalo inbred strains of rats and Wistar rats were maintained as described previously³. The procedures for obtaining tumours and regenerating livers have been described³. The growth rates of the various hepatoma lines ranged from 2-52 weeks, as measured by the amount of time required for the neoplasms to reach a diameter of 1.5 cm.

The kinetic characteristics of CTP synthetase in crude enzyme preparations and in partially (50-fold) purified extracts of rat liver and rapidly growing hepatoma 3924A were similar. The pH optima were broad, ranging from 7.0-9.0. The apparent K_m values for the ligands UTP, ATP, glutamine and GTP at pH 7.4 and 37 °C were 0.3, 0.6, 0.1, and 0.07 mM, respectively, both in liver and hepatoma 3924A crude extracts.

The specific activity of CTP synthetase in the liver of freely fed rats ranged from 4-6 nmol per h per mg protein. A comparison of

the activities of enzymes involved in the *de novo* synthesis, salvage or recycling of UMP, and in the conversion of UMP to CTP (Fig. 1), shows that CTP synthetase activity is the lowest^{15,18,19}.

In the liver tumours of slow and medium growth rate the specific activity of CTP synthetase was increased 1.8- to 3.6-fold that of normal rat livers, whereas the activity was increased from 4.6- to 11.2-fold in rapidly growing hepatomas (Table 1).

In 24-h regenerating livers, CTP synthetase activity increased twofold that observed in the liver of sham-operated control rats. This agrees with observations indicating an increase in uridylate biosynthesis in regenerating liver²⁰. CTP synthetase activity in the average liver cell of the 5-d-old rat was 31% of that of normal adult rat. Since increased CTP synthetase activity was present in the hepatomas, but not in the rapidly growing differentiating liver, CTP synthetase activity is not linked with differentiation. Since the regenerating liver has a proliferation rate similar to that of rapidly growing hepatoma 3924A (ref. 1), the elevated activity in this hepatoma (sevenfold) was higher than that in regenerating liver (twofold).

Studies in this laboratory demonstrate a marked step-up in hepatoma CTP biosynthetic capacity^{15,18}. The key enzymes participating in the *de novo* biosynthesis of UMP were increased in parallel with the increase in CTP synthetase activity and with tumour growth rate¹⁸. The salvage enzymes, uridine phosphorylase, uridine kinase, and uracil phosphoribosyltransferase, were similarly elevated¹⁹. UDP kinase was increased in all tumours irrespective of growth rate¹⁵. In contrast, the activity of the rate-limiting catabolic enzyme, dihydrouacil dehydrogenase, was decreased⁹. Thus, the programme displayed in the cancer cells provides for an increased capacity for CTP biosynthesis and a decreased capability for the catabolism of the precursors. These alterations should confer selective advantages on the cancer cells.

Note that CTP synthetase activity was also increased in slowly growing rat kidney tumour MK-3 (3.5-fold) and in three cases of human renal cell carcinoma (2.5-fold).

Our demonstration of high CTP synthetase activity in hepatomas suggests that the reprogramming of gene expression in malignant transformation and progression is linked with the

Fig. 1 Metabolic pathways for CTP biosynthesis and utilisation. Numbers in parentheses are specific activities of the enzymes (nmol per h per mg protein) at 37 °C and pH 7.4. Further details of the metabolic reactions given in schematic form in this figure are cited in the text^{1,2}. Tissue homogenates (15%, w/v) were prepared at 4 °C in 0.15 M KCl, pH 7.4. CTP synthetase activity was determined in the 100,000g supernatant fluids by measuring the conversion of 4-¹⁴C-UTP to 4-¹⁴C-CTP. The components (mM) of the incubation mixture (pH 7.4, 37 °C) were contained in 200 μ l: glycylglycine, 70; MgCl₂, 18; beta-mercaptoethanol, L-glutamine and NaF, 10; phosphoenolpyruvate and ATP, 8; GTP, 1; UTP, 2; 4-¹⁴C-UTP (60 mCi mmol⁻¹), 0.03; and supernatant fluid, 100 μ l. The assay was initiated by addition of supernatant fluid and terminated at 5-min intervals by adding perchloric acid and immersing the reaction tube in an ice-bath. Samples were neutralised with ethylenediamine tetraacetic acid-KOH solution and the potassium perchlorate removed by centrifugation. Ten microlitres of the clear supernatant fluid was applied on PEI-cellulose plates (Brinkmann) together with 20 nmols of a carrier mixture containing the mono-, di- and triphosphates of uridine and cytidine. Ascending chromatography was carried out at 4 °C in rectangular glass tanks which contained 100 ml 0.8 M ammonium sulphate as described previously²¹. CTP was located approximately 2 cm below the UTP spot as determined using ultraviolet light and autoradiography. Ultraviolet absorbing spots were cut out and placed into counting vials with scintillation fluid (Econofluor, New England Nuclear). Radioactivity was determined in a Packard Tri-Carb (Model 3390) liquid scintillation spectrometer. Protein concentrations were assayed²², using recrystallised bovine serum albumin as standard. CTP synthetase activity was linear with amount of enzyme added and time elapsed in the assay; specific activity was expressed as nmol substrate metabolised per h per mg protein.

expression of the CTP-synthesising enzyme activity. In this laboratory, 12 such transformation-linked increases in enzyme activities have so far been discovered, and they all relate to an increased potential in the channelling of metabolites to strategic biosynthetic processes. The increase in the activities of glucose-6-phosphate dehydrogenase (EC 1.1.1.49) and transaldolase (EC 2.2.1.2) provides an increased capacity for channelling glycolytic intermediates into pentose phosphate biosynthesis. Elevations in the activities of phosphoribose-1-pyrophosphate (PRPP) synthetase (EC 2.7.6.1)¹² and glutamine PRPP amidotransferase (EC 2.4.2.14)¹³ provide an increased potential for utilising ribose-5-phosphate and PRPP for *de novo* purine biosynthesis. Increases in the activities of adenylosuccinate synthetase and adenylosuccinase should yield an increased capacity for the *de novo* production of adenine nucleotides³. The elevated activity of AMP deaminase (EC 3.5.4.6)³ and IMP dehydrogenase (EC 1.2.1.14)⁶ provide an increased capability for IMP formation and its utilisation in the *de novo* biosynthesis of guanine nucleotides. The increased activities of uridine kinase (EC 2.7.1.48), uridine phosphorylase (EC 2.4.2.3), uracil phosphoribosyltransferase (EC 2.4.2.9)¹⁹ and UDP kinase¹⁵, provide an increased capacity for UTP biosynthesis. In contrast, the activities of certain catabolic enzymes are decreased in the hepatomas, including inosine phosphorylase (EC 2.4.2.1)¹⁹, xanthine oxidase (EC 1.2.3.2), uricase (EC 1.7.3.3) and thymidine phosphorylase (EC 2.4.2.4)¹⁴. The display of this transformation-linked programme indicates that an enzymatic imbalance emerged in neoplasia reflecting ordered and reciprocal alterations in gene expression. Some of these enzymes constitute promising points for attack in

the design of selective enzyme-pattern-targeted chemotherapeutic agents and offer opportunities for selectively preventing host toxicity by means of metabolite rescue²³.

Central nervous system effects of limb amputation in man

WE report here the results of an electrophysiological study of the central effects of long-standing limb amputation in man. The findings are felt to have significance for an understanding of neurotrophic mechanisms. The results show that, after amputation, the impulse-conducting ability of a peripheral nerve is severely reduced and that this is accompanied by significant changes in the evoked cortical response; in contrast, function in certain reflex pathways is apparently well maintained. This type of study complements a number of early anatomical investigations^{1,2}. In reviewing the early studies it is evident that much disagreement exists concerning the extent of the atrophy to be found in the cells of the anterior and posterior horns, and in the myelinated fibres of the anterior and posterior roots and of the ascending and descending tracts in the spinal cord. There is the added problem, common to all neuropathological studies, of deciding to what extent impulse conduction and synaptic transmission might have been interfered with. By using a functional approach our study has resolved some of these uncertainties.

The study was performed on 10 male patients, aged 11 to 47 yr. Nine patients had suffered amputation of a hand and part of the forearm and in one case a similar loss was the result of a congenital anomaly; the durations of the lesions varied from 4 months to 30 yr. In each patient the central stump of the ulnar nerve was stimulated maximally below the elbow and the compound action potential was recorded between the elbow and axilla. Recordings were also made from the somatosensory 'hand' area of the contralateral cortex using conventional techniques^{3,4}. Finally, the reflex effects of such stimulation were studied on volitional activity in the ipsilateral triceps muscle using rectification and averaging⁵. All the stimulating and recording procedures were performed with surface electrodes; these comprised chlorided silver disks or cups coated with a conducting cream. Control observations were made, using similar electrode placements, on the intact arms of the patients and on both arms (and contralateral somatosensory cortices) of 15 healthy controls. All the patients and control subjects had given informed consent for the procedures.

The results in the amputees were consistently abnormal in several respects (Fig. 1 and Table 1). First, the compound action potential in the ulnar nerve was markedly reduced on the side of the amputation, the mean peak-to-peak amplitude being only 13% of that on the control side. Maximum impulse velocities in the conducting fibres were usually normal, though low velocities in two subjects caused the mean value to be

Fig. 1 Experimental arrangement, neural pathways, and results of study in a 32-yr-old man who had suffered traumatic amputation of his right hand 3 yr previously. In each pair of recordings the upper and lower traces show the results of stimulating ulnar nerves (UN) in the intact and partially-amputated arms respectively. Stimuli were delivered at the start of each trace. Recordings from somatosensory cortex (SC) were averaged 32 times in each of two trials. The recordings from the triceps muscle (T) were made during weak voluntary contraction and several traces have been superimposed (rectified and averaged responses not shown). Vertical bar represents 10 μ V, 20 μ V and 40 μ V for recordings from cortex, peripheral nerve and triceps respectively; horizontal bar represents 40 ms except for peripheral nerve traces in which calibration marks denote milliseconds. DCN, dorsal column nuclei; Th, thalamus; triceps reflex pathway simplified.

significantly smaller. Second, the earliest negative (N_1) and positive (P_1) components of the evoked cortical responses were significantly reduced, being undetectable in four patients; in contrast, later components (N_L - P_L in Table 1) were better preserved. Finally, volitional activity in the triceps muscle was modulated to a greater extent by inputs from the amputated ulnar nerve stump than from the nerve on the intact side; this applied both to the initial inhibitory phase (40-100 ms post-stimulus) and to the succeeding excitatory phase. Control observations in normal subjects suggested that the reason for the discrepancy was that inhibition had decreased on the intact side of the amputees, presumably as a result of the extra use made of that limb after injury to the opposite arm.

These results suggest that, in normal circumstances, the functional integrity of motor and sensory axons in human limb nerves is heavily dependent on intact connections with muscle fibres and receptor tissues. Despite the severe loss of excitable axons which follows amputation, sufficient sensory nerve fibres can remain functional to elicit normal polysynaptic reflexes (involving ipsilateral motoneurons with intact axons). Finally, it is probable that there is some loss of function in the

Table 1 Comparison of responses evoked in ulnar nerve, ipsilateral triceps muscle, and contralateral somatosensory cortex following maximal stimulation of ulnar nerves in partially-amputated and intact arms of patients

		Patient limbs			P
		Control limbs (30)	Intact (10)	Amputated (10)

Acetylcholine-induced channels and transmitter release at human endplates

MYASTHENIA gravis, a disease affecting the human neuromuscular junction, is thought to result from a postsynaptic defect, namely a reduction in the number of functional acetylcholine (ACh) receptors (reviewed in ref. 1). Thus at myasthenic endplates the spontaneous miniature endplate potentials (m.e.p.ps) and impulse-evoked endplate potentials (e.p.ps) are reduced in amplitude². Furthermore, the diminished number of α -bungarotoxin binding sites^{3,4} indicates a reduction in the number of ACh receptors in the postsynaptic membrane which leads to a reduced sensitivity to ACh⁵; and preliminary experiments with voltage noise (B. Katz, R. M. & J. Newsom-Davis, unpublished) suggested that the decrease in sensitivity does not involve changes in the characteristics of the channels. We have further examined the properties of channels opened by ACh at normal and myasthenic endplates as well as some characteristics of transmitter release in the two conditions. The experiments described here indicate that the single channel conductance and the mean channel life-time are similar in normal and myasthenic muscle membranes but that there are differences in the Ca-dependence of transmitter release from normal and myasthenic nerve terminals.

Intercostal muscle from myasthenic and control patients were dissected to give a small bundle of muscle fibres, sometimes with its nerve supply. Stimulation of the nerve was via a glass capillary suction electrode. Preparations were perfused with an oxygenated medium and examined using conventional electrophysiological techniques for intracellular recording and voltage clamping. For noise experiments, ACh was applied iontophoretically from a micropipette (25–50 M Ω) positioned between the recording and voltage-clamping microelectrodes.

To study the characteristics of channels induced by ACh we have investigated miniature endplate currents, which result from the action of single packets of transmitter on the muscle membrane, and also the membrane current noise which occurs during the application of ACh⁶. As at the nerve–muscle junctions of other species⁷, m.e.p.cs at voltage-clamped human endplates vary greatly in amplitude and shape, with some m.e.p.cs being clearly composite. The decay of the faster m.e.p.cs was exponential^{8–10}, however, and these were used for subsequent analysis.

Examples of a normal and a myasthenic miniature endplate current are illustrated in Fig. 1 ($V_m = -80$ mV, $T = 23^\circ\text{C}$) which shows a semi-logarithmic plot of their decay as a function of time. Comparison of the time constant of decay of m.e.p.cs ($\tau_{\text{m.e.p.c.}}$) from normal and myasthenic endplates reveals that $\tau_{\text{m.e.p.c.}}$ is very similar in the two situations; $\tau_{\text{m.e.p.c.}}$ (normal) = 2.0 ± 0.1 ms (mean \pm s.e.), $\tau_{\text{m.e.p.c.}}$ (myasthenic) = 2.1 ± 0.1 ms. At both normal and myasthenic endplates the duration of m.e.p.cs was prolonged by hyperpolarisation of the membrane, as occurs in frog and toad muscle^{8–10}.

The correspondence of the values for the duration of $\tau_{\text{m.e.p.c.}}$ at myasthenic and normal endplates may be taken to reflect a

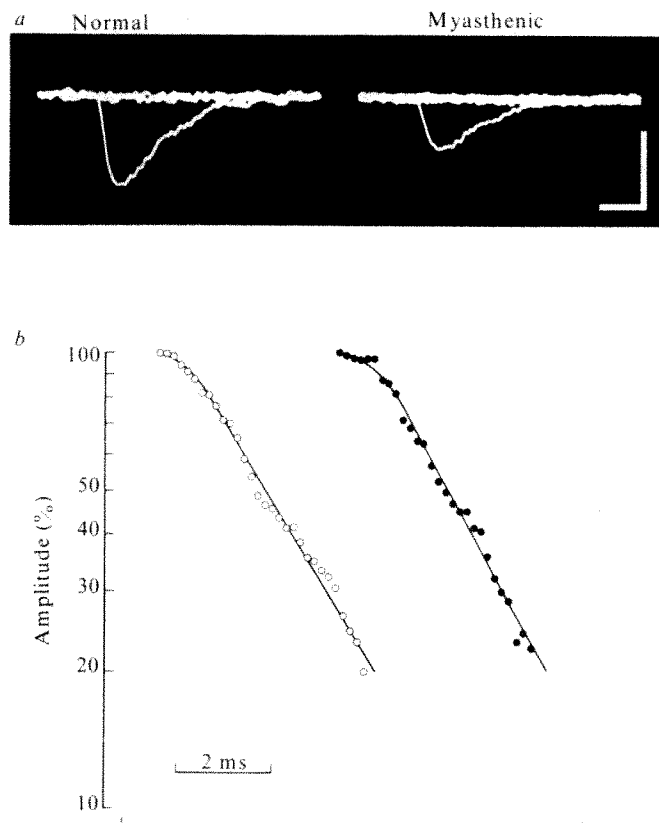

Fig. 1 *a*, Typical miniature endplate currents from normal and myasthenic human endplates. The figures are of several superimposed traces replayed from analog tape. M.e.p.cs were recorded under voltage clamp ($V_m = -80$ mV, $T = 23^\circ\text{C}$) through a 500-Hz low-pass filter which prolongs the rising phase and slightly reduces the amplitude but does not greatly affect the time constant of decay. Calibration 2 ms and 2 nA. *b*, Decay phases of the m.e.p.cs shown in *a*, plotted on semi-logarithmic co-ordinates. Straight lines through the points were fitted by the least squares method to values between 80–20% of the m.e.p.c. amplitude to give the time constant of decay. \circ , Normal $\tau_{\text{m.e.p.c.}} = 1.9$ ms; \bullet , myasthenic $\tau_{\text{m.e.p.c.}} = 1.8$ ms.

similarity in the duration of the mean open state of the acetylcholine channel in the myasthenic and normal muscle membrane, providing other factors, such as time for diffusion of acetylcholine from the cleft¹¹, are equal. It has been possible to derive certain of the properties of the single endplate channel by analysing the voltage-clamped noise which occurred during the steady iontophoretic application of ACh to endplates. In similar experimental conditions, iontophoretic application of ACh produced consistently smaller mean currents at myasthenic than at normal endplates, indicating a reduced postsynaptic sensitivity to ACh.

The mean life-time of the channel (τ_{noise}) was obtained^{6,12} from the cutoff frequency (f_c) of the power spectrum (the frequency at which the spectrum has decreased to half of the zero frequency asymptote) by fitting a single Lorentzian component of the form $S(f) = S(0)/(1 + (f/f_c)^2)$ to the spectrum, where $S(f)$ and $S(0)$ are the spectral densities at frequency f and 0 Hz respectively; hence $\tau_{\text{noise}} = 1/(2\pi f_c)$ (ms). The single channel conductance, γ , was obtained from both the variance of the current noise and the zero frequency asymptote of the spectra ($\gamma = \sigma^2/\mu_1(V_m - V_{\text{eq}})$ and $\gamma = S(0)/2\mu_1\tau(V_m - V_{\text{eq}})$, where μ_1 = mean membrane current, V_m = membrane potential, V_{eq} = equilibrium potential for ACh, σ^2 = variance of membrane current fluctuations). In estimating the conductance of the single channel, the equilibrium potential for the endplate current at the human endplate was taken as zero mV (based on unpublished observations).

The mean open time of the ACh-induced channel, obtained by analysis of current noise spectra for normal endplates was, τ_{noise} (normal) = 1.54 ± 0.05 ms (mean \pm s.e.). The comparable value for myasthenic endplates was, τ_{noise} (myasthenic) = 1.63 ± 0.1 ms, at $V_m = -80$ mV and $T = 23^\circ\text{C}$. In addition, the single channel conductance, γ , for normal and myasthenic endplates fell within

the range 20–25 pS. The similarity between the channel characteristics at normal and myasthenic endplates indicates that the properties of ACh-induced channels in myasthenia gravis are virtually unchanged.

As would be expected from earlier work on other mammals, the mean number of transmitter quanta, m , released per nerve impulse from normal and myasthenic nerve-terminals, depends on the extracellular Ca concentration. Figure 2 shows the mean quantal content of e.p.ps, obtained at typical normal and myasthenic endplates; over a range of Ca concentrations. In both cases, m increased as a function of Ca with a slope of approximately 3 on logarithmic co-ordinates. This compares with the value of approximately 3 for rat^{13,14} and for the mouse nerve-muscle junction¹⁵. Although the relation between transmitter release and external Ca concentration had the same slope value for normal and myasthenic nerve terminals, the relationship at myasthenic endplates was shifted to the left when compared with normal. Thus at any given Ca concentration in the range studied (0.3–1.0 mM) more quanta per impulse were released from myasthenic than from normal terminals. For the results from the two endplates illustrated in Fig. 1, the myasthenic terminals released approximately 8 times more quanta per impulse than the normal terminals. The size of this ratio varied from endplate to endplate in different muscles, the mean ratio being around 5:1 (myasthenic: normal) at 26 myasthenic and 12 normal endplates

Fig. 2 Relationship between extracellular calcium concentration and the mean quantal content, m , for a myasthenic endplate (●) and a control endplate (○). Each point represents the average response to 30–180 impulses. Lines with slopes of 3 have been fitted by eye through the points. At any given concentration the myasthenic nerve terminals release approximately eight times more transmitter packets. For the myasthenic curve, m is estimated indirectly from mean e.p.p.²/e.p.p. variance; for the normal curve, m is estimated from mean e.p.p./mean m.e.p.p. at each Ca concentration; additional values at 0.6 and 1.0 mM Ca were estimated from mean e.p.p.²/e.p.p. variance or from \ln (no. of impulses/no. of failures).

investigated over the range of Ca concentrations 0.25–0.7 mM (2 mM Mg). The size of the ratio became less at Ca levels greater than 0.7 mM. In the presence of 2 mM Ca (and 2 mM Mg), myasthenic terminals seem to release about twice as many quanta per nerve impulse as normal terminals. A number of possible factors can be envisaged to account for the higher levels of transmitter release from myasthenic nerve terminals. Briefly, these include: an increase in the synaptic area of myasthenic terminals (ref. 16, but see ref. 17); an increase in the level of intracellular free Ca caused either by a greater than normal influx of Ca during the nerve terminal action potential or by a diminished removal of Ca. Further studies should allow us to distinguish between these and other possibilities.

The release of a larger number of transmitter quanta per nerve impulse, from myasthenic terminals when compared with normal, may be related to biochemical studies which have shown that myasthenic muscle contains about twice as much ACh as normal¹⁸. It may be that transmitter release increases, following the impairment of transmission, as a means of 'compensating' for the reduced postsynaptic sensitivity.

We conclude that the reduction in α -bungarotoxin binding sites and in postsynaptic sensitivity at myasthenic endplates results from a loss of functional receptor-channel complexes rather than a modification of individual ionic channels. In addition, the slope value of about 3 for the Ca-dependence of transmitter release at both myasthenic and normal endplates suggests that the mechanisms underlying Ca-dependence may be unchanged. At a given Ca concentration, however, the number of transmitter packets released per nerve impulse is greater for the myasthenic than for the normal nerve terminals.

We thank Mr J. R. Belcher, F.R.C.S., Dr J. Newsom-Davis, Mr M. F. Sturridge, F.R.C.S. and Dr A. Vincent for their co-operation, and the MRC for support. We are grateful to the patients for their collaboration. S.G.C.C. is a Beit Memorial Research Fellow.

Neural induction of the 16S acetylcholinesterase in muscle cell cultures

SEDIMENTATION analysis of rat muscle acetylcholinesterase (AChE) has revealed the existence of three molecular forms, 4S, 10S and 16S (refs 1, 2). The 16S form was exclusively found in skeletal muscle segments containing neuromuscular junctions; it disappeared after denervation^{1,2} and reappeared following reinnervation either at the original endplate, or at ectopic sites. The 16S AChE may therefore be referred to as an 'endplate specific' form, but it clearly does not represent all activity at the endplate. It took several days for the disappearance of the 16S form after denervation, suggesting a postsynaptic localisation². In posterior leg muscles from rat embryos, the 16S form was absent before the

14th day of gestation; it appeared at day 15 and was relatively more abundant on day 16 (25% of the total AChE activity) than in the adult (5%). (The total AChE activity increased by a factor of 10^3 from day 16 of gestation to the adult muscle².) We present here some data concerning the synthesis of the 16S form by embryonic rat cells in culture, which demonstrate that this form is produced by muscle cell cultures on induction by neuronal elements.

Myoblasts were put in culture after mechanical dissociation of posterior leg muscles, from either 13–14- or from 18-d-old rat embryos. At the earlier age, no 16S AChE could be detected, whereas it was present in the older embryos. Spinal cord cells from

14-d-old embryos were dissociated by gentle trypsinisation or by mechanical techniques, and were plated alone, or added to myoblast cultures. The culture medium was renewed every 3 d for up to 4 weeks, when the cells peeled away from the dishes. The morphology of the cells was examined, and AChE was detected by the histochemical method of Koëlle and Friedenwald³, as modified by Couteaux and Taxi⁴, using acetylthiocholine as substrate. The molecular forms of AChE were analysed, after solubilisation in a buffer containing detergent, by sucrose gradient sedimentation². Their biosynthesis was studied after complete and irreversible inhibition (DFP), by analysing activity during recovery.

Myoblasts from 13–14-d-old embryos possessed only the 4S and 10S forms of AChE, and even after 15 d in culture, it was impossible to detect any 16S form. Similar results were obtained with cultures of spinal cord neurones. When dissociated neurones were added to a myoblast culture (2–3 h after plating, however, we observed the appearance of 16S AChE after 5 d in the mixed cultures (Fig. 1). At this stage, spots of AChE activity were detectable histochemically on the membrane of the myotubes which were coupled with the nerve cells (Fig. 2). Conversely, AChE spots were never detected on myotubes cultivated without nerve cells. In cultures coupled for 10 d, the spots gave place to typical end-plates (J. K., unpublished results). The evolution of the membranous localisation of the AChE activity suggests that the AChE spots observed at 5 d correspond to the foremost neuromuscular contacts. The negative histochemical results of Fischbach *et al.*³ may be due to the fact that the AChE activity of chicken coupled cultures is too weak to be detected by the method they use.

In contrast with 14-d-old myoblasts, muscle cells from 18-d-old embryos contained the 16S form of AChE in addition to the 4S and 10S forms, at the time of plating. The specific activity and the relative proportions of all forms remained stable in the cultures until the cells were peeling from the dishes at 4 weeks. To determine whether this was simply due to the maintenance of AChE molecules, or whether the myotubes were able to synthesise this molecular form, we inhibited all esterase activity in 8-d cultures by treatment with DFP (10^{-5} M for 1 h). Within 48 h, the AChE activity and its distribution in 4S, 10S and 16S forms had recovered. The forms appeared in succession, suggesting that the lighter molecules are precursors of the heavier ones (Fig. 3).

The results presented here clearly demonstrate that the 16S form of AChE may be synthesised by muscle cells, since the contaminating cells of myoblast cultures, fibroblasts and Schwann cells do not contain the 16S form. We never detected this form in cultures of a fibroblast cell line nor in spinal cord cultures which also contain Schwann cells. As mentioned earlier, a muscular

Fig. 1 The molecular forms of acetylcholinesterase in cell cultures of *a*, spinal cord neurones; *b*, myotubes and *c* mixed cultures. 5×10^6 myoblasts or cells from one spinal cord were plated in 50-mm dishes. In mixed cultures, one spinal cord was added to a myoblasts culture 2–3 h later. Cells were grown in 80% MEM, 10% medium 199, 10% horse serum and 0.5% chick embryo extract medium. After 5 d cells were scraped from the dishes, gathered and homogenised using a Potter homogeniser in a solution containing 1 M NaCl, 5×10^{-2} M $MgCl_2$, 10^{-2} M Tris-HCl pH 7 and 1% Triton X-100. The homogenate was centrifuged at 20,000g for 30 min at 4 °C and the supernatant assayed immediately for AChE activity and analysed on a sucrose gradient. AChE activity was determined at 20 °C by the method of Ellman *et al.*⁵. Sedimentation ultracentrifugation on linear sucrose gradients (5–20%) in presence of the homogenising buffer was performed on a Spinco LII 65 ultracentrifuge, using a SW60 rotor at 125,000g for 15 h at 2 °C. Fractions were collected and assayed immediately for enzymatic activities. B-Galactosidase (16S) and horse liver alcohol dehydrogenase (4.8S) were used as enzyme markers. The recovery of AChE activity after sedimentation procedures was higher than 80%.

Fig. 2 Areas of high activity of AChE visualised as 'spots' on the membranes of young myotubes by the histochemical method of Koëlle and Friedenwald⁶ as modified by Couteaux and Taxi⁷. Fixation was in neutral formaldehyde 5% for 5 min, followed by incubation in Koëlle's medium using AChE as substrate at pH 5 for 12 h. Cultures of myoblasts obtained from 13–14-d-old embryos coupled for 5 d with cord cells of 14-d-old embryos. The cell culture conditions were as in Fig. 1 $\times 800$.

Fig. 3 Restoration of AChE activity after DFP inhibition in cell culture of myotubes from 18-d-old embryos. Here 10⁶ myoblasts were plated in 60-mm dishes. Cells were incubated for 1 h in presence of 10⁻⁵ M DFP in the culture medium to inhibit AChE activity. Such treated cells were washed in order to eliminate excess free DFP and incubated in the culture medium for periods indicated. Other experimental conditions were as in Fig. 1. ■, Cells 7 h after DFP incubation; Δ, cells 14 h after DFP incubation; ▲, cells not incubated with DFP or cells 48 h after DFP incubation.

localisation was implied by the slowness of its disappearance in denervation experiments, but this was not conclusive for its biosynthesis.

From studies of neuroblastoma cell cultures⁴ it has been concluded that the 4S form is a precursor of the 10S form. The present observations also suggest that these forms might in turn be precursors of the 16S molecule.

The most interesting feature of the 16S form of AChE is that its synthesis by muscle cells requires an interaction with neuronal elements, since it only appears in mixed cultures, or in cultures from 18-d-old embryo cells, which have made contact with neurones *in vivo* before being plated. In this second case, the continued synthesis of 16S AChE by these cells, in the absence of neurones, seems paradoxical in view of the disappearance of this form from denervated adult muscles. The experimental situations are, however, so different that it is difficult to interpret this phenomenon and it might well reflect the plasticity of embryonic nerve-muscle interactions.

It would be extremely useful to understand how the 16S molecule is constructed and if non-catalytic elements are included in this complex structure, in addition to knowing how their synthesis and assembly are regulated. The observations reported here not only demonstrate the muscular origin of the 16S acetylcholinesterase and its induction by neuronal elements, but the two types of cultures described provide excellent models for future investigation of the nature of the interaction involved.

We thank Professor G. Buttin and Dr M. Lambiotte for culture facilities and Ms P. Cloup, M. Orouet and D. Dufo for technical assistance. We are grateful to Dr J. Massoulié for helpful discussions and critical comments. Effects of [Ca²⁺] and [Mg²⁺] on the decay of miniature endplate currents

THE endplate current at the neuromuscular junction is initiated by the combination of acetylcholine (ACh) with its receptor. The current rises rapidly to a maximum, and then decays exponentially¹. The rate of decay of the endplate current (e.p.c.) depends on membrane potential; hyperpolarisation lengthens the decay phase^{2,3}. A plausible hypothesis for this is that the rate of disassociation of the ACh from the receptor depends on the voltage gradient through the membrane⁴. The membrane potential consists of three components: the voltage gradient through the membrane itself and the surface potentials at the two membrane-solution interfaces. The surface potentials are thought to be negative, owing to an excess of negatively-charged groups on the membrane phospholipids. An elevation in the divalent ion concentration in the extracellular solutions reduces the negativity of the external surface potential, either by binding to the phospholipids or by screening the charges. A lowering of the negativity of the external surface potential leads to a corresponding increase in the voltage gradient within the membrane (over shorter periods than for phospholipid flip-flop to occur). This leads to the prediction that alterations in the extracellular [Ca²⁺] or [Mg²⁺] are likely to change the time course of the e.p.c. Our experiments were designed to test this hypothesis.

We studied spontaneously occurring miniature endplate currents (m.e.p.cs) to avoid problems caused by raised divalent ion concentrations, such as, changing quantal outputs from stimulated nerves or alterations in the shape of the presynaptic action potential. The two-microelectrode voltage-clamp technique was used at the neuromuscular junction of the sartorius muscle of the frog, *Rana pipiens*¹. The microelectrodes were inserted close to the centre of the junction, as judged by the rise times of the miniature endplate potentials (m.e.p.ps). One electrode monitored the membrane potential, the other passed the clamping current. Both were filled with 4 M potassium acetate. Experiments were carried out both in the presence and absence of 10⁻⁶ g ml⁻¹ neostigmine methylsulphate, which has been shown to slow the decay phase of the m.e.p.cs without altering their voltage dependence⁵.

The results of one experiment in the presence of neostigmine are shown in Fig. 1. The [Ca²⁺] concentration was varied tenfold and m.e.p.cs were recorded between -83 mV and -150 mV. From the recordings, decay half-times ($\tau_{1/2}$) were measured. The tenfold increase in [Ca²⁺] caused roughly the same slowing of the decay as a hyperpolarisation of 20 mV. In six additional experiments, four in the presence of neostigmine and two in its absence, there was a consistent slowing of the decay time course of the m.e.p.cs in elevated [Ca²⁺]. (The magnitude of this effect seemed somewhat smaller in the neostigmine-free preparations.)

To test whether this effect was specific to Ca²⁺ or a more general characteristic of divalent cations, the experiments were repeated varying the Mg²⁺ concentration. One example in the absence of neostigmine is shown in Fig. 2. In this experiment there was a slowing of the decay of the m.e.p.cs equivalent to a 12-mV hyperpolarisation when the [Mg²⁺] was altered from 1 to 10 mM. Similar effects were seen in six additional experiments (two more in the absence of neostigmine and four in its presence).

Since Mg²⁺ and Ca²⁺ produce similar effects in lengthening the decay phase of the m.e.p.cs it seemed possible that the effects might be produced exclusively by the screening of the surface charges by the divalent ions in the solution. The relation between membrane surface charge density, σ (charges cm⁻²), and membrane surface potential, ψ (V), in solutions with different con-

concentrations of univalent, i^+ , and of divalent, i^{2+} , ions (mol cm^{-3}) is

$$\sigma^2 = \frac{\epsilon k T}{2\pi} \left[[i^+] [\exp(Q\psi/kT) + \exp(-Q\psi/kT) - 2] + [i^{2+}] [2\exp(Q\psi/kT) + \exp(-2Q\psi/kT) - 3] \right] \quad (1)$$

where k is the Boltzmann constant, T is temperature in degrees Kelvin, Q is the charge on the electron, and ϵ is the permittivity of water⁵.

The data in Fig. 1 show that a tenfold increase in $[\text{Ca}^{2+}]$ produces an effect that could be attributed to a 20-mV decrease in ψ . By setting up equation (1) for the two divalent ion concentrations, it is possible to solve the pair of simultaneous equations for ψ . In 1 mM $[\text{Ca}^{2+}]$, ψ is about -100 mV, which would be produced by a charge density, σ , of about 1 charge per 93 \AA^2 . Such a high surface potential seems unlikely and in other experiments the change in ψ produced by a tenfold rise in extracellular divalent ion concentration seems to be even greater. Consequently it is unlikely that the changes in ψ could be produced by screening alone, there is probably also some binding of divalent ions to the membrane. If we assume that ψ in 1 mM Ca^{2+} is -75 mV ($\sigma = 1$ charge per 181 \AA^2), a 20-mV fall in ψ would follow a 20% decrease in the number of excess negative charges on the membrane surface (to $\sigma = 1$ charge per 302 \AA^2).

Any alteration of the surface potential will change the concentration profiles of ions between the bulk solutions on the two sides of the membrane, and thus alter the single channel conductance. In all experiments in 10 mM Mg^{2+} and Ca^{2+} we noticed a decrease in the average peak height of m.e.p.s. This result agrees with experiments showing, by noise analysis, a decrease in the single channel conductance at increased $[\text{Ca}^{2+}]$. (C. Lewis and C. F. Stevens, personal communication.)

Inspection of Figs 1 and 2, together with data not reproduced, suggests that the lines connecting the data points are not parallel, they often seem to converge or diverge at the most negative holding potentials. This could be an artefact caused by the distribution of the endplate, which extends for an appreciable fraction of a length constant along the fibre. Therefore, when the

fibre is clamped away from the resting potential, there is a voltage gradient between the current-passing electrodes and the margins of the endplate. If the resting potential falls, as is almost inevitable following repeated periods of current injection, then the voltage gradient increases, and this may lead to errors in relating the observed decay half-times to the potential set by the clamp near the centre of the endplate.

In summary, the results are consistent with the idea that the membrane at the muscle endplate has a net negative external surface charge. The lowering of the surface potential by screening and/or binding of divalent ions increases the voltage gradient within the membrane. The increased voltage gradient within the membrane slows the time course of the decline of the ACh-induced conductance change. These results have implications for other work. For example, experiments in which the Ca^{2+} and Mg^{2+} levels are manipulated to change the quantal outputs from the stimulated nerve terminals will also be changing the time course of the post-junctional current flows, unless the total concentrations of divalent cations are maintained at a constant

Fig. 2 Effects of changing membrane potential and $[\text{Mg}^{2+}]$ on the $\tau_{1/2}$ of the m.e.p.c. Solutions are as in Fig. 1b with Mg^{2+} substituted for Ca^{2+} . Bars represent \pm s.e.m. ●, 1 mM Mg^{2+} ; ○, 10 mM Mg^{2+} .

level. The post-junctional effects must be considered carefully when evaluating the results. The effects of negative surface charges near the ACh receptor will change the local concentrations of all charged substances near the surface of the membrane according to the Boltzmann distribution:

$$[i^N]_0 = [i^N] \exp[-NQ\psi/kT] \quad (2)$$

where $[i^N]$ is the concentration of I in the bulk solution $[i^N]_0$, the concentration at the membrane surface, and N is the valance. For example, if the ψ at the outer membrane surface is -70 mV, a positive univalent ion, like ACh, will be 15.4 times more concentrated at the surface. A positive divalent ion, like tubocurarine, will be concentrated more than 200-fold.

Phospholipase A and the mechanism of action of aldosterone

ALDOSTERONE stimulates Na transport across the renal tubule and this effect is also seen in 'model' epithelia such as amphibian urinary bladder, skin and colon¹⁻³. This hormone is thought to act by inducing the formation of proteins through nuclear transcription⁴. Their nature and actions are unknown but it has been suggested that one such protein may act like a 'permease' and increase the permeability of the apical side of the epithelial cells or they could stimulate the activity of the Na transport pump. Goodman *et al.*⁵, have suggested that "some key enzyme" which increases the turnover of fatty acids may be involved and this could be phospholipase. We report here the identification of phospholipase A in toad bladder and frog skin epithelial cells and in their incubation media. Mepacrine, an inhibitor of phospholipase A, blocked the response to aldosterone on Na transport.

Toad urinary bladder and frog skin were used. Phospholipase activity was determined in tissue extracts and fluids using phosphatidyl[N-methyl]¹⁴C choline 60mCi mmol⁻¹ (Amersham-Searle) as a substrate (Table 1). Phospholipase activity was determined in tissue or cell homogenates by incubation, in 2-4 ml of Ringer solution containing 2-3 nmol of ¹⁴C-phosphatidylcholine for 2 h at 22 °C. Enzyme activity in the fluids bathing the frog skin and toad bladder preparations was determined by incubating the tissues in Ringer solution and after a specified time removing 4 ml of fluid from both sides, and incubating this with the labelled substrate. The enzyme reaction was terminated by addition of a 2:1 chloroform-methanol mixture and 1 ml of the aqueous phase was counted in a liquid scintillation counter.

Homogenates of the toad bladder and frog skin had phospholipase activity and this was localised in the separated epithelial cells (Table 1). No significant activity

was found in the liver or skeletal muscle of the toads. Gentle homogenisation of the isolated epithelial cells resulted in partial release of the enzyme in the first supernatant fraction (Table 1). The remaining activity appeared in the aqueous following sonication of the pellet. If, however, the tissues were initially sonicated, nearly all the activity could be identified in the supernatant separated by high speed centrifugation. These results suggest that while the activity may be sequestered, it is readily released, and is soluble.

We incubated bladder and skin preparations in Ringer and assayed the fluid that bathed each surface (Table 2). These solutions could also hydrolyse ¹⁴C-lecithin and the total amount of activity that was released in 3 h far exceeded that stored in the tissues. However, it is possible that endogenous unlabelled lecithin could be interfering with the tissue assays, resulting in an underestimate, though this seems unlikely in the supernatants separated by high speed ultracentrifugation. We also identified the enzyme material in the mucosal fluid bathing the toad's colon (which transports Na *in vitro*³) (Table 2), and in its urine (1 ml (14 samples) hydrolysed 90 ± 14 p mol ¹⁴C-lecithin⁻¹). Some bacteria form phospholipases so that we also included either gentamicin (Schering; 100 µg ml⁻¹) or penicillin (Pfizer, 100 U ml⁻¹) plus streptomycin (Pfizer, 100 µg ml⁻¹) in the bathing and incubation media, but they did not decrease the accumulated enzyme activity. In the bladder the rate of secretion was asymmetrical, more appearing in the mucosal than serosal fluid. In the skin a consistent pattern was not seen.

The products of the reaction of the enzyme secreted by the toad bladder epithelial cells were identified using thin

Fig. 1 The possible pathways for phosphatidylcholine metabolism and the products (*) which were identified in response to the action of the phospholipase secreted by amphibian epithelia. To identify the products of phospholipase action the lipid and aqueous phases were each subjected to thin layer chromatography. The two phases were separated and taken to dryness under reduced pressure. The remaining material was dissolved in 200 µl of methanol and 20 µl of this solution was applied to thin layer plates. Chromatographic separation of the phospholipids (lipid phase) was carried out in a solvent mixture consisting of chloroform, methanol, water (65:25:4) on silica gel G plates. The fractions were visualised by exposure to iodine vapour and identified by comparing them to appropriate reference substances. After the disappearance of the iodine staining the areas of the thin layer corresponding to phosphatidylcholine and lysophosphatidylcholine were scraped and eluted with methanol directly into vials and counted in the liquid scintillation spectrometer. The quantity of silica gel of each scraped area was constant. The relative mobilities (R_f) of these phospholipids in the solvent system used were: phosphatidylcholine, 0.34; lysophosphatidylcholine, 0.15. The labelled substrate, ¹⁴C-phosphatidylcholine, when chromatographed on thin layer plates alone was found to be >99% pure. The water soluble products were chromatographed on cellulose sheets (Kodak) using a solvent system of chloroform, methanol, ammonia (65:45:8) and visualised by spraying with a modified molybdate solution and exposing the plates to ultraviolet light for 30 min. The areas corresponding to phosphorylcholine, L-α-glycerophosphorylcholine and choline were scraped off and eluted in counting vials as described above. The R_f values were: phosphorylcholine, 0.02; L-α-glycerophosphorylcholine, 0.13 and choline, 0.40.

layer chromatography (Fig. 1). Small amounts of choline were present but the principal component in the aqueous fraction behaved chromatographically like L- α -glycerophosphorylcholine. The formation of this lipid could be prevented by the presence of 5 mM deoxycholate, which inhibits lysolecithinase⁶. Lysophosphatidylcholine (lysolecithin) accumulated in the lipid phase in the presence of deoxycholate but could not be detected in its absence. Thus the primary product of the enzymatic reaction is apparently lysophosphatidylcholine, which is formed as a result of the action of phospholipase A on phosphatidylcholine, but this is apparently normally converted to water soluble L- α -glycerophosphorylcholine. The 'lecithin-lysolecithin cycle' has previously been identified in homogenates of toad bladder⁷.

It has been suggested that a phospholipase may be involved in the action of aldosterone on epithelial membranes⁸. This could involve an increased rate of turnover of the enzyme or an increase in its activity. The demonstration of such changes may be expected to be a problem as the enzyme is readily inactivated. Thus in the bladder the secreted activity less than doubles between 3 and 18 h incubation (Table 2). Indeed, we were unable to demonstrate a change in secretion of the enzyme in response to aldosterone in the bladder. However, in another target tissue, the frog skin, accumulation increased fourfold. Frog skin moults in the presence of aldosterone, though both responses are superimposed and involve the same types of cell⁹. The morphological change may favour the release or stability of the enzyme.

Phospholipase A is inhibited by mepacrine^{9,10}; at 10^{-6} M mepacrine inhibited the *in vitro* activity of the enzyme secreted by the toad bladder by 35%. Mepacrine also completely inhibited the effects of aldosterone on Na

The toads weighed about 200 g. The bladders (two hemi-bladders, about 200 mg whole tissue) were perfused with Ringer to remove the blood. The bladder epithelial cells were separated by incubating each hemi-bladder sac preparation in Ringer (in mM, NaCl, 111; KCl, 3.35; CaCl₂, 2.7; NaHCO₃, 4.0 and glucose 5.0) in the absence of added Ca²⁺ and containing 2 mM EGTA, for 75 min. The cells were separated by gently massaging the sac, pooled and centrifuged for 15 min at 2,500g. Pieces of frog skin epithelium were separated by exposing the inner surface to collagenase (Sigma, 250 µg ml⁻¹) under about 50 cm hydrostatic pressure for about 2 h. The isolated bladder epithelial cells were resuspended in 2 ml of a solution containing 4 mM NaHCO₃ and 5 mM CaCl₂ (pH about 8.0), and incubated with 2–3 nmol of phosphatidyl[N³-methyl-¹⁴C]choline for 2 h at 22 °C. The solution was then extracted with 19 ml of 2:1 chloroform-methanol and 1 ml of the aqueous was counted in a scintillation counter. Assays were corrected for a reaction 'blank' which was small and amounted to about 0.4% of the total phosphatidylcholine present. Frog skin epithelium (20 cm², 424 mg whole skin) was assayed similarly. Results are means ± s.e. Numbers of experiments carried out shown in parentheses.

Corium side 3 h (10)	67±17
Toad colon: mucosal side 3 h (5)	39±6
Effect of 10 ⁻⁶ M aldosterone; (total secretion)	
Toad bladder; 18 h incubation*	
Control (6)	260±55
Aldosterone (6)	274±60
Frog skin; 18 h incubation	
Control (10)	318±25
Aldosterone (10)	1,267±198†

Toad hemi-bladders (and colons) were prepared as sacs. The short-circuit current (µA per 100 mg) for the 18 h incubation was 158±20 for the control, and 555±62 for aldosterone. The frog skins were either tied onto lucite cylinders (surface area 10 cm² = 200 mg) or for testing the effects of aldosterone, prepared in Ussing-type chambers (3 cm² = 60 mg). The short-circuit current after 18 h was (µA cm⁻²) 17±2 in the control and 42±8 in the aldosterone treated skin. Values are mean ± s.e., pmol hydrolysed in fluids bathing 100 mg tissue. Number of experiments shown in parentheses.

*We were also unable to see a stimulation of enzyme activity by aldosterone even for the shorter time period of 3 h either initially or following an 18 h preincubation.

fatty acids which are substrates for prostaglandin synthesis. It was therefore also interesting to observe that mefenamic acid and indomethacin which inhibit prostaglandin synthetase¹¹ also inhibited the action of aldosterone on Na transport, though the response to vasopressin was unaffected (Table 3).

The effect of aldosterone on transepithelial Na transport thus seems to be related to the actions of two enzymes, phospholipase A and prostaglandin synthetase. Both of these are known to be present in this tissue and are known to be involved in the common chain of events that mediates (this paper and ref. 12) prostaglandin synthesis. The mechanism of aldosterone action is unclear, but it could be inducing the formation, activation, or release of phospholipase A. It has recently been shown that RNA and protein synthesis are necessary for expression of phospholipase action in mouse fibroblasts¹³. We do not know by which process prostaglandins could be influencing the response but some are known to increase active Na transport across these membranes^{14,15}.

This work was supported by the US NSF. Dr L. A. Barker kindly helped and advised us in the identification of phospholipase A.

Inactivation of interferon mRNA in the shutoff of human interferon synthesis

INDUCTION of interferon synthesis in cultured cells by $rI_n \cdot rC_n$ has been intensely studied because of its attractiveness as a model for gene expression in mammalian cells and its possible significance to medicine. Exposure of human fibroblast FS-4 cells to $rI_n \cdot rC_n$ results in interferon (IF) synthesis which persists for 6 h and then abruptly shuts off^{1,2}. The rapidity of this shutoff indicates that the cessation of IF mRNA transcription is unlikely to be the primary control. Moreover, studies with metabolic inhibitors³⁻⁷ have suggested that a post-transcriptional event is involved. To evaluate the role of post-transcriptional control in the shutoff of IF production, we measured directly the level of IF mRNA activity in a strain of human fibroblast HF 926 cells during the IF induction process. This was achieved by the development of a highly efficient and reproducible heterologous whole cell translational system. We report here that, using this system, we have found a significant decrease in the IF mRNA activity during the shutoff of IF protein synthesis.

The translational system consists of the direct application of isolated human RNA to Syrian hamster embryo (SHE) cells. Absolute species specificity between the human and hamster interferons allows for the bioassay of human IF

Table 1 Effect of actinomycin-D pre-incubation and RNA facilitators on interferon mRNA Translational efficiency

Treatment	Incubation time (h)	Facilitator	IF titre (units ml ⁻¹)	% Efficiency
None	-	CaCl ₂	13	6.25
Actinomycin D	5	CaCl ₂	22	11.0
Actinomycin D	5	DEAE-Dextran	4	2.0
Actinomycin D	10	CaCl ₂	22	11.0
Actinomycin D	15	CaCl ₂	41	20.0

Confluent monolayers of Syrian hamster embryo cells (SHE) in 75 cm² flasks with $3-4 \times 10^6$ cells per flask were treated with 0.065 μ g ml⁻¹ actinomycin D in maintenance media for the times indicated. After actinomycin treatment, 50 μ g ml⁻¹ cytoplasmic RNA, obtained from $rI_n \cdot rC_n$ -induced HF-926 cells by a modified Penman procedure¹³, were applied to the SHE cells with either 50 μ g ml⁻¹ of DEAE-dextran or 30 mM CaCl₂ in 5 ml of HEPES-phosphate-buffered saline (PBS) buffer, pH 7.0. After incubating at 37 °C for 1 h, the HEPES-PBS buffer was removed from all flasks and replaced with 10 ml of maintenance media. Translation was allowed to proceed for 5 h and the media was collected for assay.

that has been translated in the heterologous SHE cells. Translation is dependent on application of the RNA with a substance which facilitates the RNA uptake. Both DEAE-dextran⁸ and CaCl₂ (refs 9, 10) have been used successfully to enhance the infectivity of viral nucleic acids. We adapted these procedures for mRNA. CaCl₂ was a more effective facilitator than DEAE-dextran in both translational efficiency and reproducibility (Table 1). Pretreatment of the recipient SHE cells with actinomycin-D before addition of human IF mRNA was not essential, but this treatment increased translational efficiency, particularly with long preincubation times. Presumably, this enhancement is the consequence of endogenous mRNA degradation in the SHE cells with the resultant increase in translational capacity. Efficiency of translation can be estimated by comparing the amount of human IF translated by the SHE cells from a given quantity of added human RNA to the amount of IF

Fig. 1 Cytoplasmic RNA extracted by a modified Penman procedure¹³ from HF 926 cells 3 h after induction with $rI_n \cdot rC_n$ was mixed with cytoplasmic RNA from mock induced HF 926 cells at the shown ratios. The total concentration of RNA in each sample was 50 μ g ml⁻¹. All points represent the average of duplicate assays.

produced from an equivalent number of human cells from which the RNA was isolated (Table 1). For instance, in a typical experiment, one 1/2 gallon roller bottle (690 cm^2 , $2\text{--}3 \times 10^7$ cells) of induced human cells produced approximately 10,000 IF units, whereas approximately 600 IF units (6% efficiency) were produced by the SHE cells on translation of the mRNA isolated from this roller bottle. Depleting the SHE cells of Ca^{2+} before addition of human RNA also increases IF mRNA translation (Table 2). Interferon activity was always associated with the poly A mRNA fraction retained on oligo dT-cellulose and not with the flow-through fraction. No IF production was found when RNA from uninduced human cells was used in translation.

When cytoplasmic RNA extracted from $\text{rI}_n\text{-rC}_n$ -induced HF 926 cells was applied to Ca^{2+} -depleted SHE cells using the CaCl_2 precipitation technique, the IF translation was found to be independent of the absolute RNA concentration. In the concentration range of $10\text{ }\mu\text{g ml}^{-1}$ to $100\text{ }\mu\text{g ml}^{-1}$, the IF yield remained constant. But, when RNA from induced cells was diluted with varying amounts of carrier RNA while keeping the total RNA concentration constant at $50\text{ }\mu\text{g ml}^{-1}$, IF production varied linearly with the proportion of IF mRNA in the applied RNA sample (Fig. 1). These observations can be explained on the basis of a limitation in the RNA uptake of SHE cells. If the uptake capacity is limited, then the absolute amount of mRNA translated by the SHE cells is fixed when the amount of applied RNA exceeds this capacity. Therefore, in saturating conditions (over $10\text{ }\mu\text{g RNA per ml}$) the SHE cell translational system responds proportionately not to absolute dosage of IF mRNA but rather to its relative concentration in the preparation (equivalent to 'specific biological activity' of IF mRNA).

Kinetics of the IF protein synthesis measured in HF 926 cells after 1 h induction with 0.4 mM ($130\text{ }\mu\text{g ml}^{-1}$) $\text{rI}_n\text{-rC}_n$ in physiological salt buffer (0.15 M NaCl , 0.01 M PO_4 , 0.001 M MgCl pH 7.2), is shown in Fig. 2a. The rate of IF synthesis reached a maximum at about 3–4 h after induction and was largely shut off by 8 h. In many of these experiments, especially when a lower concentration of $\text{rI}_n\text{-rC}_n$ was used for induction, there was no detectable synthesis at 8 h. These findings corroborate those of Vilček and his colleagues¹¹ for FS-4 cells.

Total cytoplasmic RNA was extracted according to a modified Penman procedure^{12,13} from the same cells and at the same time points as in Fig. 2a. After deproteination, each RNA sample was adjusted to a concentration of $50\text{ }\mu\text{g ml}^{-1}$, 30 mM CaCl_2 and translated in Ca^{2+} -depleted SHE cells. The kinetics of IF mRNA activity are given in Fig. 2b. Similar results were obtained when DEAE-dextran was used to facilitate RNA uptake. The appearance of IF mRNA in the human cells after exposure to $\text{rI}_n\text{-rC}_n$ is very rapid, peaking at 2–3 h post-induction. More significantly, there is an abrupt decline in IF mRNA activity which corresponds to the shutoff of the IF synthesis.

Sehgal *et al.* have shown that interferon shutoff can be prevented when an RNA inhibitor such as actinomycin D or 5,6-dichloro-1- β -D-ribofuranosylbenzimidazole is given to the cells after induction⁴. In these conditions, synthesis of IF can

Fig. 2 HF 926 cells in 1/2 gallon roller bottles were induced with $0.4\text{ mM rI}_n\text{-rC}_n$ for 1 h then re-fed with D-MEM with 2% foetal calf serum. Media was collected for measuring IF titres and the cells extracted for RNA at 2½, 5½, 7½, 11, and 14 h. Similar results were obtained in two additional experiments. a, Rates of IF synthesis following induction. b, IF mRNA activity following induction.

persist beyond 20 h indicating that the human IF mRNA is a stable species with a half life on the order of 15 h. In view of their finding, it is unlikely that the rapid decline in IF mRNA activity is the result of a natural decay process but is more likely to be the result of a specific inactivation event.

IF mRNA activities during the induction of IF have been examined in two studies by whole cell translational systems. Kronenberg and Friedman¹⁴ measured $\text{rI}_n\text{-rC}_n$ induced L cell IF mRNA by translation in Vero cells. But, they did not attempt explicitly to correlate the IF mRNA activities with IF protein levels nor did they attempt to study the shutoff process. At 3 h after induction, when no IF was produced, they detected high levels of IF mRNA whereas at 16 h, when IF was synthesised at maximal rate, they observed a reduction in the levels of IF mRNA. These observations indicate that the system of IF induction in mouse cells is different than in human cells and, therefore, complicate comparisons between these two cell types. Furthermore, since no IF mRNA determinations were made during the shutoff of mouse IF, no conclusions can be made concerning the relationship between IF shutoff and IF mRNA activities.

Reynolds and Pitha¹⁵ studied both human IF production and IF mRNA activities using the avian cell translational system originally developed by DeMayer-Guignard *et al.*¹⁶. In contrast to our findings they did not observe a decrease either in the rate of IF production or in the levels of IF mRNA. More recently, Raj and Pitha¹⁷ observed that IF production in human fibroblasts declines 90% by 6–9 h after induction.

An important consideration in the interpretation of these data is the validity of the translational system. An ideal translational system should translate exogenous mRNA with fidelity and high efficiency, thereby reflecting the functional state of the IF mRNA in the originally induced cell. Translation of the human mRNA by another mammalian cell, such as the hamster, should offer the best prospects in this respect.

Work is in progress to identify the regulatory elements involved in the inactivation of IF-mRNA. Such a repression mechanism may be of broader biological relevance.

These results were reported at the 77th annual meeting of the American Society for Microbiology¹⁸. We thank Mr Stanley Lin for many helpful discussions. This research was supported in part by US NIH (grant GM 166066).

Note added in proof: Sehgal *et al.* and Cavaliere *et al.* using the *Xenopus laevis* oocyte translational system have also observed^{19,20} the rapid decline in IF mRNA activity during the shutoff of human IF synthesis.

Table 2 Effect of Ca^{2+} -depletion on the translation of human interferon mRNA in SHE cells

Treatment	IF titre (units ml^{-1})
Control (media only)	20
Dulbecco's PBS-HEPES (30 min)	19
Ca^{2+} -free PBS-HEPES (30 min)	76

Translation was as for Table 1 except that before addition of the RNA, the SHE cells were either untreated or incubated with Ca^{2+} -free or normal PBS-HEPES buffer for 30 min.

Bleomycin causes release of nucleosomes from chromatin and chromosomes

THE antibiotic bleomycin is effective against certain human neoplastic diseases¹. Interaction of purified DNA with bleomycin results in the release of free bases from the DNA backbone^{2,3}, disruption of phosphodiester linkage, and destruction of the deoxyribose moiety⁴. Bleomycin-induced DNA strand scissions, both single- and double-strand, were found in bacterial as well as in mammalian systems^{5,6}. But, all previous work on bleomycin has dealt with DNA molecules extracted from treated cells, and analysed on sucrose density gradients. This is not sensitive enough to probe the action of bleomycin with respect to chromatin structure. It is now known that chromatin is composed of a number of repeating subunits connected by a continuing DNA duplex analogous to 'beads on a string'⁷. The bead-like structure, termed nucleosome or nu-body, contains 140 base pairs and eight histone molecules^{8,9}. The DNA between nucleosomes, about 40-60 base pairs in length, is referred to as the linker DNA. Both DNAs in the nucleosomes and in the linker are susceptible to nuclease digestion, but the latter is more sensitive¹⁰⁻¹². We have analysed the effects of bleomycin on chromatin with special reference to the characterisation of the breakage sites in a number of mammalian cell systems. The results reported here indicate that bleomycin is one of the few non-enzymatic chemicals which can be used to study the chromatin structure, and that the action of bleomycin is not identical to that of nucleases—bleomycin does not digest nucleosome DNA but attacks only the linker DNA.

When nuclei isolated from cultured Chinese hamster cells (line CHO) were incubated with various concentrations of bleomycin, followed by deproteinisation and gel electrophoresis on agarose, a characteristic series of DNA bands was obtained (Fig. 1). DNA isolated from untreated nuclei showed a high molecular weight (gel 3), indicating that endogenous nucleases had no significant effect on native DNA. The DNA isolated from the nuclei treated with higher concentrations of bleomycin contained more DNA fragments with lower molecular weight than that from

Fig. 1 Agarose gel analysis of DNA digested *in situ* with bleomycin. Approximately 10^7 CHO nuclei isolated using the method described previously²⁰ were incubated in 400 μ l of reaction mixture containing 15 mM Tris-HCl, pH 8.0, 0.34 M sucrose, 0.5 mM EDTA and 15 mM 2-mercaptoethanol and various concentrations of bleomycin at 22 °C for 2 h. The reaction was terminated by the addition of an equal volume of solution containing 0.15 M NaCl, 15 mM EDTA, 50 mM Tris-HCl, pH 8.25, 0.3% sarcosyl NL 97. The mixture was treated with 100 μ g ml⁻¹ of heated (100 °C for 5 min) RNase A at 37 °C for 1 h. DNA was extracted by deproteinisation with phenol saturated with 0.15 M NaCl, 0.1 M EDTA followed by chloroform:isoamylalcohol (24:1,v/v), and precipitated with 2.5 volumes 100% ethanol. Agarose (1.4%) was made in E buffer containing 40 mM Tris-HCl, pH 8.0, 5 mM Na-acetate, 1 mM EDTA. Electrophoresis was run in E buffer at 4 mA per gel. Gel (1) *Hae*III-digested PM 2 DNA, (2) *Hind*III-digested PM 2 DNA, (3-9) CHO DNA; (3) control, no bleomycin added, (4) 1.5 μ g/ml, (5) 15 μ g ml⁻¹, (6) 300 μ g ml⁻¹, (7) 1 mg ml⁻¹, (8) 2 mg ml⁻¹, and (9) 3 mg ml⁻¹ bleomycin.

nuclei treated with lower concentrations of bleomycin, indicating that the fragmentation of nuclear DNA is dose dependent (gels 4-9).

The molecular weight of each band (Fig. 1) was determined by three methods. (1) Construction of a calibration curve by plotting the migration distance of the PM 2 phage DNA fragments digested by restriction enzymes *Hind*III and *Hae*III (Fig. 1, gel 1, 2) against their molecular weights (data not shown). The lengths of the second band (from the bottom of the gels) to the 5th band, averaged from three independent experiments, were 343 ± 7 , 535 ± 15 , 693 ± 15 , and 890 ± 10 base pairs, respectively. These values correspond well to a monomer unit length of 175 ± 4 base pairs. (2) Linear regression analysis of the logarithms of the molecular weight of the restriction fragments plotted against mobilities. The repeated unit length was found to be 170 ± 8 base pairs. (3) Subtracting the length of each band from that of the next higher band. Using this method, the unit length was found to be 182 ± 10 base pairs. The average of these three determinations yielded a unit length of 175 ± 8 base pairs, which is in good agreement with the nucleosome unit length reported by other investigators^{13,14} using nuclease digestions. Bleomycin, therefore, acts on chromatin in a manner analogous to that of nucleases.

Further analyses showed, however, that the modes of action on chromatin DNA between nucleases and bleomycin are not exactly the same. Nucleases have been shown

Fig. 2 Gel electrophoretic patterns of DNA isolated from bleomycin-treated CHO nuclei. CHO cells were labelled with ^3H -TdR ($0.5 \mu\text{Ci ml}^{-1}$, 22 Ci mmol^{-1}) for 24 h. Procedures for isolation of nuclei and digestion by bleomycin are described in Fig. 1. ●, Control, no bleomycin; △, $1.5 \mu\text{g ml}^{-1}$ bleomycin for 5 h; ■, $300 \mu\text{g ml}^{-1}$ for 5 h. a, DNA samples were electrophoresed in non-denaturing conditions as described in Fig. 1. b, Corresponding samples as run in denaturing conditions, that is, 5% acrylamide in 99% formamide²¹. The marker DNAs (○) shown in (b) are *Hind*III- and *Hae*III-digested PM 2 DNA fragments^{22,23}. The arrows represent the corresponding numbers of base pairs (a) or nucleotides (b) as calibrated from the same DNA markers co-electrophoresed.

to digest intra-nucleosomal DNA and produce a series of bands with a multiplicity of 10 nucleotides as analysed by a denaturing gel¹⁵⁻¹⁷. We did not obtain similar results when bleomycin was used.

Figure 2 shows gel electrophoretic patterns of radioactively-labelled DNA isolated from bleomycin-treated nuclei or control nuclei. The specific activity of DNA was approximately $20,000 \text{ c.p.m. } \mu\text{g}^{-1}$, sensitive enough to detect an amount as small as 5 ng. The control sample gave no detectable amount of DNA with molecular weight less than 5,000 base pairs. The treated sample showed DNA in a series of bands with multiplicity of 175 base pairs as described previously.

When the same samples shown in Fig. 2a were denatured and separated on denaturing gels, a characteristic pattern emerged (Fig. 2b). In the bleomycin-treated samples, only bands with sizes of 50, 175 and 360 nucleotides were present. The minor band (50 nucleotides in length as analysed by extrapolation of the calibration curve) was not present in the undenaturing DNA gel. This fragment must, therefore, have come from a higher molecular weight, double-stranded duplex containing single-stranded nicks.

That the double-stranded, high molecular weight DNA contains single-strand nicks can also be seen by comparing the same sample ($300 \mu\text{g ml}^{-1}$, 5 h) electrophoresed in non-denaturing (Fig. 2a) and denaturing conditions (Fig. 2b). Figure 2a shows that about 50% of the counts migrated with molecular weights higher than 500 base pairs. But, when this sample was denatured and separated in denaturing gel, the high molecular weight DNA (>500 base pairs) disappeared and was replaced by monomeric and dimeric fragments. From these results, we conclude that the high molecular weight DNA duplex contained single-strand breaks spaced regularly, probably every 50, 175 or 360 nucleotides apart.

We detected no multiplicity of 10 nucleotides on the gels. This indicates that the nuclease-sensitive sites within nucleosomes are not sensitive to bleomycin. An explanation for this phenomenon is that bleomycin is more specific

in its recognition of sequence or structure of the DNA helix than are nucleases. Previously, we have reported that DNA with molecular weight less than approximately 12 nucleotides is resistant to bleomycin degradation, regardless of the sequence¹⁸. If DNA within the nucleosomes is kinked every 10 base pairs as proposed by Crick and Klug¹⁹, or embedded within protein molecules, then the intranucleosomal DNA may become resistant to bleomycin activity, so that no internal nicks can be created. Our interpretation is that bleomycin induces damage only in the internucleosomal linker DNA, and that the 50 nucleotide pieces probably came from nicks in the linker DNA at or near the adjacent nucleosomes. We also found that several mammalian cells in addition to CHO responded to bleomycin in a similar manner, and that the antineoplastic protein, neocarzinostatin, also yielded DNA degradation products similar to those of bleomycin. We believe that these drugs will be very useful tools in the study of chromatin structure.

Dissociation of 'hybrid' isozymes on electrophoresis

HETEROMERIC or 'hybrid' isozymes can be readily demonstrated by electrophoretic techniques. They can be observed, for example, in individuals who are heterozygous for alternative alleles at an autosomal locus determining a multimeric enzyme or where multiple loci are involved in the determination of a multimeric enzyme. Heteromeric forms can also be generated by techniques such as somatic cell fusion, and by dissociation and recombination *in vitro*. The number of heteromeric isozymes displayed by a particular enzyme is related to its subunit composition. For example, in a heterozygote a dimeric enzyme exhibits one heteromeric isozyme and two homomeric isozymes, whereas a

Fig. 1 Starch gel electrophoresis of SOD at 8 °C and at 37 °C using a Tris, EDTA, maleate, MgCl₂ buffer system at pH 7.4. Electrophoresis was carried out for 17 h at 5 V cm⁻¹ at 8 °C and 3.5 V cm⁻¹ at 37 °C. Temperature was regulated during electrophoresis by circulating water at the appropriate temperature through electrically insulated metal plates which were in close contact with the gel surface. The gels were stained using MTT 0.1 mg ml⁻¹ and phenazine methosulphate 0.05 mg ml⁻¹ in Tris/Cl buffer, pH 8.0 applied as an agar overlay. The samples are liver extracts from (a) an individual of phenotype SOD_s 1 and (b) an individual of phenotype SOD_s 2-1. The most cathodal zone of activity is SOD_M which does not show the same genetic variation.

tetrameric enzyme displays three heteromeric isozymes in addition to the two homomeric forms. Thus, the number of heteromeric isozymes provides a valuable method of assessing the number of subunits making up active enzyme molecules and indeed this approach has recently been used in a survey of the subunit structures of 66 different human enzymes¹. It was found that heteromeric isozymes usually occur as described here, but there are occasional exceptions where the expected 'hybrid' isozymes are unusually weak or absent. We have investigated one component of the electrophoretic separation system—that is, temperature—and its influence on the occurrence of heteromeric isozymes using soluble superoxide dismutase (SOD_s) as a test case. This was prompted by a report that this dimeric enzyme is

readily dissociated at high temperatures²; also, the heteromeric isozymes of SOD_s can be conveniently studied by electrophoretic methods. Our results suggest that temperature has a crucial effect on the occurrence of the heteromeric isozymes of this enzyme.

SOD, which catalyses the disproportionation of superoxide radicals, exists in two forms in eukaryotes³. One form, SOD_s, found in the cytosol, is a dimeric copper-zinc protein with a molecular weight of 32,000. The mitochondrial form, SOD_M, is a tetrameric manganese protein with a molecular weight of about 72,000. An electrophoretically slow genetic variant of the soluble enzyme, designated SOD_s 2-1 and attributable to heterozygosity for a variant allele SOD_s¹ (ref. 2), and the common allele SOD_s¹, has been identified⁴. In heterozygotes, three isozymes are observed under standard electrophoretic conditions. The two outer zones representing the homomeric forms, and the middle zone the heteromeric ('hybrid') form containing polypeptides determined by each allele.

A liver extract from an individual of the SOD_s 2-1 phenotype was subjected to electrophoresis in starch gels at various temperatures ranging from 8–55 °C. At 8 °C, the usual three-banded pattern was observed. At 20–30 °C, a three-banded pattern was also observed; but, whereas the homomeric isozymes were of usual activity, the heteromeric form was much less active. At temperatures above 35 °C, two bands were observed with mobilities corresponding to the two homomeric forms and displaying normal activity. The heteromeric isozyme was not present (Fig. 1). Similar results were obtained with man-mouse hybrid material derived from somatic cell fusion and from *in vitro* dissociation and recombination (Fig. 2).

A simple explanation for these findings would be that heteromeric isozymes of SOD_s are more heat sensitive than homomeric forms. Heating the SOD_s isozymes (40 °C, 17 h) in the gels using the technique of McAlpine *et al.*⁵, subsequent to their separation by electrophoresis at 8 °C, did not, however, lead to any noticeable loss of activity. Furthermore, heating a crude tissue extract at 70 °C for up to 3 h, followed by electrophoresis at 8 °C, revealed that the homomeric and heteromeric isozymes lose activity at the same rate. Thus, it seems that the disappearance of the heteromeric isozymes during electrophoresis is not due to heat lability.

A more likely explanation (similar to that proposed to account for the disappearance on electrophoresis of the asymmetric 'hybrid' forms of haemoglobin^{6,7}) is that the dimeric SOD_s isozymes are in rapid equilibrium with their constituent polypeptides at elevated temperatures:

Fig. 2 Electrophoresis of SOD_s at 8 °C (5 V cm⁻¹) and at 45 °C (3 V cm⁻¹) using the procedure detailed in Fig. 1. Samples: a, human liver; b, a 'hybrid' preparation of man and mouse SOD_s prepared by *in vitro* dissociation and recombination; c, mouse liver.

Fig. 3 Two-dimensional electrophoresis of man-mouse 'hybrid' SOD₅ isozymes. In each case electrophoresis in the first dimension was at 8 °C. In the second phase electrophoresis was carried out at 8, 27 and 40 °C. Conditions for electrophoresis and SOD detection as described in Fig. 1.

On electrophoresis, this equilibrium is disturbed due to the separation of the unlike forms, so that there is a progressive depletion of the heteromeric ('hybrid') isozyme:

In ordinary temperature conditions, the dissociation-reassociation process is presumably much less rapid, and the heteromeric SOD₅ isozyme persists.

This interpretation has been investigated using a two-dimensional technique. In the first dimension, separation was carried out at 8 °C (that is, the usual condition for SOD₅ electrophoresis) and then in the second dimension at 8 °C, 45 °C or some intermediate temperature. In one series of experiments, samples containing three isozymes of SOD₅ were separated by electrophoresis at 8 °C and then the pieces of gel containing the middle band (the heterodimeric isozyme) were cut out and subjected to electrophoresis at 45 °C. In each case—regardless of whether the heterodimer was derived from a SOD₅ 2-1 heterozygote, a somatic cell hybrid or from *in vitro* dissociation and recombination of man and mouse SOD₅—this single band was found to generate two isozymes of equal intensity and with electrophoretic mobilities identical to the corresponding homodimers. In another series of experiments, the second phase of electrophoresis was carried out using all three isozymes (the two homodimers and the intermediate heterodimer). With increasing temperature in the second phase of electrophoresis, there was a coincident apparent increase in the rate at which the heteromeric isozyme generated the homomeric bands (Fig. 3). Thus, it seems that temperature has a crucial influence on the appearance of the heteromeric isozymes of SOD₅ after electrophoresis.

We have made preliminary investigations into the effects of temperature on a limited number of other enzymes which exhibit heteromeric isozymes, but so far no example of dissociation during electrophoresis which is as clear-cut as that described for SOD₅, has been seen. A wide range of enzymes, however, remains

to be investigated as well as many other factors, such as pH, buffer ion concentration and coenzyme binding, which might affect the dissociation of isozymes during electrophoresis. Also, the condition of the sample may influence the appearance of heteromeric forms, since it has recently been shown that, although an asymmetric 'hybrid' haemoglobin band is not usually seen—for example, in A-S and A-C heterozygotes—on conventional electrophoresis, this type of band is observed when the haemoglobins are reduced and maintained in anaerobic conditions during electrophoresis⁸.

It seems particularly worthwhile to investigate any multimeric enzymes (or other proteins) which are found to show exceptional isozyme patterns in respect of 'hybrid' forms in case the hybrids are being lost by dissociation during the separation process. For instance, in the case of galactokinase there is evidence for a dimeric structure⁹, but a heteromeric isozyme with a mobility intermediate between the human and mouse isozymes has not been observed in hybrid cell lines¹⁰. Another example is enolase, a dimeric enzyme determined at three separate loci, coding for the polypeptides α , β and γ . The heterodimers $\alpha\beta$ and $\gamma\beta$ are observed after electrophoresis together with the homodimers $\alpha\alpha$, $\beta\beta$ and $\gamma\gamma$, but the expected heterodimer $\alpha\gamma$ has not been detected in either human or rat tissues¹¹.

In every unusual case, however, it will be necessary to bear in mind other reasons for the absence of heteromeric isozymes after electrophoresis. In the case of enzymes determined by X-linked loci, where only one X chromosome is functioning in each cell, there is no opportunity for unlike polypeptides to come together to form hybrid isozymes. This is illustrated by the glucose-6-phosphate dehydrogenase isozymes in females of the AB phenotype: hybrid isozymes have been observed in oocytes from such females, in which both X chromosomes are active, but not in other tissues¹². Differences in gene expression from one cell type to another also results in the absence of heteromeric forms. For example, lactate dehydrogenase (LDH) AC and BC hybrids are not found in testicular tissue. This is because only the LDH_C locus

is active in primary spermatocytes, whereas the LDH_A and LDH_B loci are expressed in other cells of the testis¹³.

Sometimes, there may be stereochemical reasons why dissimilar polypeptides do not form a hybrid. A possible example is the rare genetic variant of human LDH¹⁴. The multimeric enzymes which exhibit mitochondrial and cytoplasmic forms, determined by separate loci, may provide other examples of stereochemical constraints. Presumably, the gross structural difference between SOD_S and SOD_M—one a dimer, the other a tetramer—prevents the formation of a cytoplasmic-mitochondrial hybrid form. But the reasons why other multimeric enzymes with a similar subcellular distribution (for example, malate dehydrogenase, aspartate aminotransferase, malic enzyme) do not exhibit cytoplasmic-mitochondrial hybrid isozymes, are obscure. In most cases, these isozymes have the same subunit structure and in at least one case (aspartate aminotransferase), a fair degree (about 48%) of homology in amino acid sequence^{15,16}. Perhaps the hybrid forms occur *in vivo* but are dissociated *in vitro*.

N-methylphenylalanine at the N-terminus of pilin isolated from *Pseudomonas aeruginosa* K.

AUTOMATED amino acid sequence analysis of pili protein isolated from the multi-piliated 2PfS mutant of *Pseudomonas aeruginosa* strain K (PAK)¹ has shown that *N*-methylphenylalanine is the amino terminus. These pili, which mediate the infectious process of several *Pseudomonas* bacteriophages², are composed of one protein subunit, pilin, of molecular weight 17,800 (ref. 1). Mass spectroscopy (MS), 270 MHz proton magnetic resonance spectroscopy (PMR), ultraviolet absorption spectroscopy, gas/liquid chromatography (GLC) and thin layer chromatography (TLC) have demonstrated the identity of the phenylthiohydantoin (PTH) derivative of the amino terminal amino acid (PTH-X) to be identical with synthetic PTH-*N*-methylphenylalanine.

N-methylphenylalanine was synthesised by methylation of tertiary butyloxycarbonyl-phenylalanine dicyclohexylamine salt with methyl iodide in tetrahydrofuran in the presence of sodium hydride for 24 h at 21 °C (ref. 3), with subsequent removal of the carboxyl- and amino-protecting groups by treatment with aqueous citric acid, pH 3, and 50% (v/v) trifluoroacetic acid/dichloromethane, respectively. Reaction of *N*-methyl-

phenylalanine (90 mg) with 5% (v/v) phenylisothiocyanate in pyridine (2.4 ml) at 55 °C for 1 h gave the phenylthiocarbamyl derivative, which after drying in a vacuum, was converted to the PTH derivative by reaction with 1 M HCl (1 ml) at 80 °C for 10 min, the crude product being obtained by extraction with ethyl acetate (3 × 1 ml). Recrystallisation from diethyl ether afforded colourless crystals m.p. 113 °C.

Since the PTH-*N*-methylphenylalanine synthesised coeluted as a single peak on GLC with PTH-X, the product of the first Edman degradation of PAK/2PfS pilin (Fig. 1), and cochromatographed as a single spot on silica gel TLC (E. Merck, precoated) using two solvent systems (*R_f* 0.94 with 1,2-ethanedichloride:acetic acid 30:7 (v/v)⁴ and *R_f* 0.33 with chloroform:ethanol, 98:2 (v/v)⁵), MS, PMR and ultraviolet absorption spectroscopy were carried out to compare the two compounds further. To obtain sufficient PTH-X for PMR analysis

Fig. 1 GLC of (a) PTH-X (2% of the product from the first Edman degradation of 5 mg (280 nmol) pilin, and (b) PTH-*N*-methylphenylalanine, together with a number of standard PTH-amino acids (5 nmol of each). Separations were made on a Beckman GC-45 gas chromatograph fitted with a 1.2 m × 2 mm internal diameter column of 10% SP-400 on 100-120 mesh Supelcoport (Supelco), using helium carrier gas at 40 ml min⁻¹.

Fig. 2 MS of PTH-*N*-methylphenylalanine (a) and PTH-X (b). Both spectra were obtained on 10 μ g or less of sample by direct probe, 70 eV electron impact ionisation at an initial ion source temperature of 150 °C, using an AEI MS50 high resolution mass spectrometer in conjunction with a DS50 computer.

(0.2 mg), a combined total of 35 mg (2 μ mol) pilin were subjected to one Edman degradative cycle.

The MS of the two compounds is shown in Fig. 2. A molecular ion of $m/e = 296$ and major fragments of $m/e = 205$, 91 and 77 were evident in both spectra.

Similarly, Fig. 3 provides a comparison of the compounds' PMR spectra. The peaks downfield from 6.7 to 7.4 p.p.m. represent the two phenyl rings in the PTH derivative. The peak at 4.45 p.p.m. is due to the α -carbon proton, whereas the peak at 3.33 p.p.m. is due to the β -carbon protons. The singlet at 3.42 p.p.m. is indicative of the *N*-methyl protons.

Ultraviolet absorption spectra of the compounds showed that both have a high $\epsilon_{245}/\epsilon_{269}$ ratio of 0.64 compared with values at about 0.4 for PTH derivatives of other amino acids, with the exceptions of 0.72 for PTH-*N*-phenylthiocarbonyl-lysine and

0.67 for PTH-proline⁴. In addition, the ϵ_{269} molar absorption coefficient for the synthetic compound is lower at 13,500 than the usual value of around 16,000 for these amino acid derivatives⁴.

Attempts to regenerate and detect by amino acid analysis *N*-methylphenylalanine by hydrolysis of PTH-X and the synthetic derivative were unsuccessful. Neither acidic hydrolysis with 5.7 M HCl at 110 °C for 24 h or 57% HI at 127 °C for 20 h, nor alkaline hydrolysis with 0.2 M NaOH/0.1 M Na₂S₂O₄ at 127 °C for 4 h (ref. 6) yielded *N*-methylphenylalanine. To be able to detect this amino acid the method of Coggins and Benoiton⁷ in which a halved buffer and ninhydrin flow through the reaction coil, resulting in a double reaction time with ninhydrin, was used.

Whereas *N*-methylphenylalanine is a novel component of protein, it has been shown to be a constituent of the peptide antibiotic Staphylomycin S, produced by *Streptomyces virginiae*⁸. Pettigrew and Smith⁹ have reported the finding of dimethylproline as a blocking group at the amino terminus of *Crithidia oncopelti* cytochrome C557 and speculated on the possibility of other α -*N*-methylated amino acids existing in proteins. In the case of PAK/2Pfs pilin, however, the *N*-methylphenylalanine did not act as a blocking group to sequence analysis but merely presented a new PTH amino acid, which was not readily identified. Edman degradation in subsequent cycles proceeded normally with no obvious drop in efficiency between the first and second cycles. This is not surprising, since proline, the only other secondary amine usually encountered in protein sequence work, is not known to interfere with the process. (These sequence data are beyond the scope of this communication and will be presented separately.)

Finally, although conventional amino acid analysis of the 24-h 5.7 M HCl protein hydrolysate failed to detect the new amino

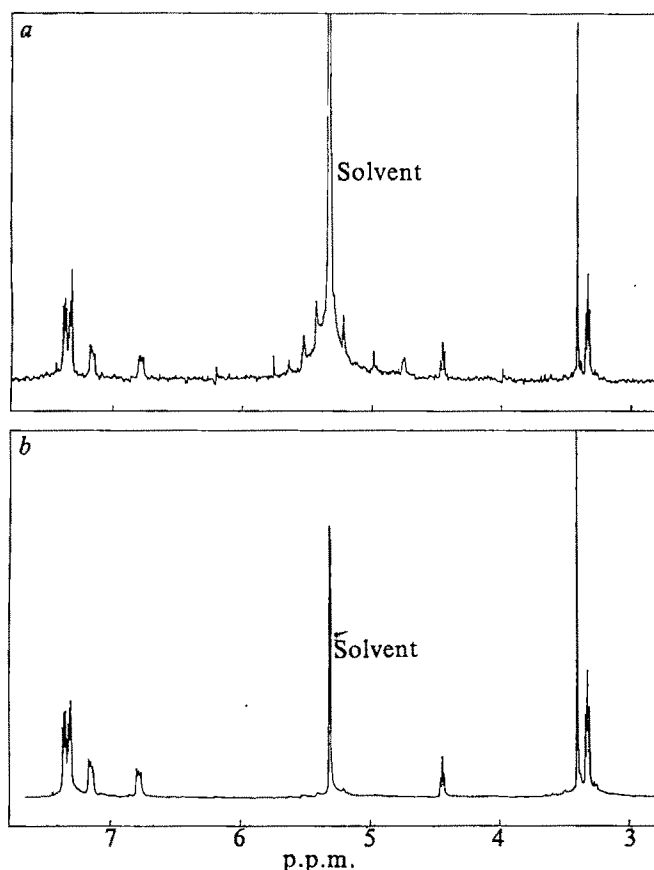

Fig. 3 PMR spectra of PTH-X (a) and PTH-N-methylphenylalanine (b). Both samples, 0.2 and 1.0 mg respectively, were washed with 99.8% D₂O and dried *in vacuo* (twice) before being dissolved in 0.4 ml CD₂Cl₂-d₂. The spectra were recorded with a Bruker HX 270 superconducting NMR spectrometer at 270 MHz and ambient temperature. Comparative peaks were adjusted to similar height. Chemical shifts are reported in p.p.m. downfield from tetramethylsilane.

acid¹, application of the method of Coggins and Benoiton⁷ permitted the detection of 1 mol *N*-methylphenylalanine per 12.6 mol leucine. Thus, on the basis of the previously reported amino acid analysis¹, which established 14 leucine residues per polypeptide (molecular weight 17,800), it is clear there is only one *N*-methylphenylalanine per polypeptide and, as already demonstrated, it occupies the amino terminus of the molecule.

Chaos in the Zhabotinskii reaction

THE Belousov–Zhabotinskii reaction is a chemical Bonhoeffer–van der Pol circuit, that is, a relaxation oscillator that can be run as both an astable and a monostable ‘flip-flop’^{1–3}. Apparently the reaction also belongs to the slightly more complicated class of ‘universal circuits’⁴ as introduced by Khaikin^{5,6}. Oscillators of this type not only show ‘smooth’ and ‘relaxation type’ oscillations^{5,6}, but also ‘chaotic’ oscillations⁴. As evidenced by the simplest equation of this type⁷, both ‘spiral type’ and ‘screw type’ chaos²⁰ are possible in such systems. We present here preliminary evidence for the occurrence of screw-type chaos in the Zhabotinskii reaction.

The system was investigated in isothermal, continuous stirred flow conditions. The initial concentration of reactants was 1.8 mM of MnSO₄, 5.6 mM H₂SO₄, 0.36 M malic acid, and 45 mM potassium bromate. The volume of the reaction mixture was 36 ml. Specifically, the reaction mixture contained 50 parts of a solution ‘I’ (containing 0.34 g MnSO₄·H₂O, 153 g H₂SO₄ and 54 g malic acid l^{–1}) and 6 parts of a solution ‘II’ (70 g KBrO₃ l^{–1}). The two solutions were continuously injected by means of a peristaltic pump (Pharmacia P–3) at the same (50:6) ratio; total flow rate was 1 ml min^{–1}. The temperature was kept at 30 °C (±0.01). The volume was kept constant by means of an overflow mechanism. The electrochemical potential was measured by means of a platinum and an Ag/AgCl electrode. The system was allowed 15 min to reach a ‘stationary’ regime. A subsequent recording over 25 min is presented in Fig. 1. Similar recordings were obtained over several successive hours.

The Zhabotinskii reaction is an (about) 15-variable reaction system^{8–11}. The electrochemical potential is not uniquely related to one of these variables⁹. Only a limited amount of information can, therefore, be gained from a single measured curve. All that can be said is that the reaction is not periodic over the time interval shown (and over any time interval measured so far). If the observed oscillation corresponds to a limit cycle, the latter is bound to be of ‘complicated’ type. A complicated limit cycle (being multiply folded in state space) is, however, in itself an indicator for existing chaos. This is because the presence of such a limit cycle in most cases implies the very ‘folding’ of a cross-section through the trajectorial flow (see refs 4, 7, 20) that is also sufficient for truly non-periodic behaviour¹².

In realistic systems, exogenous perturbations are unavoidable. This means that a limit cycle of large periodicity will not be detectable if its ‘region of dominating influence’ (where the temporal behaviour is similar to that on the limit cycle) in state space is small. For then very small perturbations (for example, even the small errors of a highly accurate numerical integration routine) suffice to prevent the system from locking into the periodic regime. The longer the period, the greater this sensitivity to perturbations. On the other hand, a very large ‘pseudo-random’ period (possessing perhaps 10¹⁰ intermediate maxima,

Fig. 1 Irregular oscillation of electrochemical potential in the Zhabotinskii reaction in isothermal continuous stirred flow conditions. *V*, electrochemical potential is plotted against *t*, time.

which is not unrealistic) is, for all practical purposes, equivalent to a genuinely non-periodic oscillation.

If there is exogenous 'noise' in an apparently chaotic system, the only way to detect an intrinsic chaotic component is through looking at the trajectorial flow in state space. If the flow, although being 'blurred', remains roughly confined to a sub-manifold of detectable shape, and if this shape is one of a few basic types²⁰ known to be chaos-producing in deterministic conditions, then it is possible that the system is also capable of purely 'endogenous' chaos.

Sometimes a single measured variable (or combination of variables, respectively) suffices for this proof. This is the case in spiral-type chaos⁴, for example, if the variable with the largest amplitude is the one that is measured. If subsequent recorded maxima ('amplitudes') are then plotted, each as a function of the respective last, a Li-Yorke-type map is obtained which indicates chaos^{12,13}. Other sub-manifolds in state space (like that determining screw-type chaos^{7,20}) are not so easily detectable, however. The next step in the present investigation will therefore be to simultaneously record several observables, so that three-dimensional stereoscopic pictures of trajectorial flow in observation space can be obtained.

The simplest screw-type chaotic flow⁷ has the temporal behaviour shown in Fig. 2. The time course of the first variable is reminiscent of the flow of Fig. 1. This allows the prediction that typical screw-type chaos can be found in the Zhabotinskii reaction.

The first evidence that the Zhabotinskii reaction is an oscillator of the universal circuit type was provided by the finding of 'double oscillations' in continuous stirred flow conditions^{14,15}. At that time, the dynamical implications of this result were still unknown, however. Later, A. T. Winfree (personal communication) suggested that his observation of a 'meandering' core in a non-stirred excitable version of the Z reagent¹⁶ was evidence for chaos. In the meantime, a similar phenomenon has been found in computer studies of a two-variable excitable medium (ref. 17, Rössler and Kahlert, in preparation); while two variables are sufficient for chaos in non-stirred reaction systems¹⁷⁻¹⁹, three variables are necessary in well-stirred systems. The finding that 'non-planarity' of a limit cycle in three- or higher-dimensional state space (so that a 'folded over' regime is possible) is all that is required for chaos⁴ immediately suggested that virtually all realistic chemical oscillators should be capable of chaos. Olsen has found evidence for spiral chaos

Fig. 2 Time behaviour of the three variables of the simplest screw-type chaotic oscillator. Numerical simulation of the following system of three coupled ordinary differential equations: $\dot{x} = -y - z$, $\dot{y} = x + 0.55y$, $\dot{z} = 2 - 4z + xz$. Initial conditions: $x(0) = y(0) = z(0) = 1$. $t_{\text{end}} = 152$. For a stereoscopic picture of the same flow see ref. 20.

in the horse-radish peroxidase reaction^{21,22}. Hudson's group, who had done many experiments on the Zhabotinskii reaction in continuous stirred flow conditions²³, also took a second look and found evidence of chaos²⁴. They interpreted their result in terms of the chaotic trajectorial flow described in ref. 4 which corresponds to spiral-type chaos. The present evidence for screw-type chaos (first communicated in ref. 25) does not preclude the possibility of spiral-type chaos in the Zhabotinskii reaction. On the contrary: in abstract systems, the observation of either screw- or spiral-type chaos virtually guarantees that the other type is also possible with slightly changed parameter values²⁰.

We thank Art Winfree for discussions.

Note added in proof: Two-dimensional plots (electrochemical potential against potential of a bromide ion sensitive electrode) obtained in the meantime range from the picture of a fluctuation-triggered monoflop (pseudochaos) to a picture looking like a two-dimensional projection of screw-type chaos.

matters arising

The Thera eruption and Late Minoan-IB destruction on Crete

PICHLER and Schiering¹ argue that there is no relationship between the paroxysmal volcanic eruption of Santorini in the Bronze Age and the Late Minoan-IB destructions on Crete, as proposed by Marinatos². The arguments for or against such a relationship are not as clear as they contend. There are several suggestions in their paper which may be disputed and they have been selective in their evidence. Contrary to their major point, the resolution of the pottery chronology is not sufficiently precise to infer a 50-yr gap between the destructions on Crete and the main eruption. The complexities of the relationship between IA and IB pottery styles, recently reviewed by Luce³, have been ignored. There is evidence that the two styles are in part synchronous³ and there is considerable doubt as to their stratigraphic distinction³⁻⁵.

Acrotiri was originally destroyed by earthquakes and evacuated before the eruption^{6,7} and was then apparently revisited by a group reconstructing the town, but was never reinhabited⁷. The gap between the earthquakes and the eruption is often quoted as less than two years^{1,3,5}, but this is speculation. The evidence on Santorini does not preclude a series of plausible events such as precursory earthquakes and even small eruptions, which may have discouraged reoccupation for an extended period. We agree with Pichler and Schiering that the eruption was probably very short, but challenge their interpretation of the deposits on Santorini. The occurrence of 3m lithic blocks is not evidence of the onset of caldera collapse, or even circular or polygonal fractures. There are several alternative interpretations, including ejection of lithic blocks during phreatomagmatic explosions, blocks eroded from the vent wall, blocks picked up by mud-flows or pyroclastic flows from the volcano's slopes⁸. The largest lithic blocks on Santorini are predominantly found in deposits interpreted by Bond and Sparks⁸ as mud-flow not ash-flow deposit. Bond and Sparks⁸ also describe late-stage flood deposits and ignimbrites which were emplaced before substantial collapse had begun. A gap of unknown duration between the eruption

and caldera collapse cannot be discounted.

The confidence with which Pichler and Schiering assert that the ash layer was of negligible thickness on Crete is unwarranted. Ninkovich and Heezen⁹ provided firm evidence of the large scale of the eruption and of a high probability of ash-fall on Crete. Their evidence cannot be discarded, as later papers have confirmed the correlation of the Minoan ash layer^{10,11} in RV Vema cores from the Lamont-Doherty Geological Observatory by the presence of the 7,000-yr BP sapropel and chemical analyses. Although the ash layers in cores V10-50 and V10-58 are undoubtedly overthickened by slumping, a reasonable thickness of ash has to accumulate initially to produce a slump. Pichler and Schiering claim to have succeeded in the most difficult of geological tasks, to show that visible remnants of the Minoan ash do not exist on Crete. Their dismissal of the presence of volcanic glass fragments in Cretan soils¹²⁻¹⁴ as due to the use of imported pumice lumps in Minoan households and workshops is unconvincing, and we suggest that this evidence supports ash-fall on Crete. Similarly, to dismiss the possibility of catastrophic tsunamis on the basis of an unpublished theory is unacceptable. Finally we note that the 'isoseismic' data in their Fig. 2 concerning the 1926 earthquake, published over 40 yr ago, seems to be a function of the density of population and hence observation points as well as possible tectonic blocks. We believe, therefore, that more evidence is required to test the theory of Marinatos² relating the Minoan demise to volcanic activity. There

are three time gaps to be considered: that between the earthquake(s) which destroyed Acrotiri and the onset of the eruption, that between the destruction of Acrotiri and devastation of Crete and that between the eruption and caldera collapse, and possible resulting tsunamis. The many uncertainties in the length of these time intervals is such that the volcanic theory cannot be discarded.

Possible solar eclipse effect 23 October 1976

LILLEY and Woods¹ operated magnetometers at 10 sites in central and eastern Australia during the solar eclipse of 23 October 1976, and reported a possible eclipse effect at two stations (labelled H and J in their Fig. 1) lying in the path of totality. They observed an event at approximately the time of totality (0638 UT) but pointed out that the event had not moved from west to east at the expected rate. As an eclipse affects the ionosphere over a relatively large area one would not expect the few minutes of totality to produce such a pronounced effect as indicated by their records.

In South Africa the eclipse was partial and of limited duration, starting at sunrise (~ 0420 UT). The records of the magnetic observatories Hermanus (34°S, 19°E) and Grahamstown (33°S, 27°E) should be free of eclipse effects at the time of totality in Australia (0638 UT). The declination variations as recorded at these two observatories over the period illustrated by Lilley and Woods are shown in Fig. 1. It is evident

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered.

Fig. 1 The declination records for Grahamstown and Hermanus, and the Grahamstown-Hermanus difference curve, plotted on the same scale as used by Lilley and Woods¹. All records are plotted relative to arbitrary zeros.

that the magnetic field in South Africa was slightly disturbed during the interval 0620–0640 UT when the eclipse occurred in Australia. The 0711 event mentioned by Lilley and Woods is also present although the relative amplitude is smaller than in Australia. The Grahamstown-Hermanus difference graph shows a rapid variation at 0628 UT compared to 0638 UT in Australia. The event reported by Lilley and Woods could, therefore, have been a small eastward travelling disturbance. One should, however, be careful not to attribute all sudden changes in the difference curves to a phase shift. High frequency variations at site J are clearly more damped than the corresponding variations at site H. The form and smoothness of the difference curves are in fact determined to a large extent by the relative frequency responses at the two sites, and not by phase shifts, except in the case of the S_q variations. Similar effects can be seen in the Hermanus-Grahamstown comparison. High frequency response at Hermanus is markedly lower than at Grahamstown.

We conclude that the event reported by Lilley and Woods is a manifestation of a minor magnetic disturbance. The variations observed at the Gngangara observatory in Western Australia should give more information on the suggested eastward travelling event.

PO Box 32,
Hermanus 7200,
South Africa

LILLEY AND WOODS REPLY—We accept Scheepers' evidence for some widespread minor magnetic activity at the time of the eclipse in south-east Australia. If the source currents for this activity flowed in the overhead ionosphere they (like the S_q currents) may be perturbed by lowered ionospheric conductivity in an eclipse shadow, and we are now examining the

data from our line of instruments for such an effect. We agree with Scheepers that such an ionospheric effect may be difficult to distinguish from local differential induction.

Climatic interpretation of $\delta^{18}\text{O}$ and δD in tree rings

THERE has been considerable interest^{1–5} in, and some controversy^{5–7} over the use of the stable isotopes of oxygen and hydrogen in tree rings as measures of past climate. We point out here that variations in isotopic values from the whole ring (or a number of rings) may be in part a function of variations in ring width. As a consequence, whole ring isotope estimates of past climate will not be independent of ring width estimates of past climate. This is a direct result of the relative constancy of either early- or late-wood width in many tree species and of the differences in isotopic composition between early and late wood.

In many species of tree, much of the variation in ring width from year to year is in either the early-wood or the late-wood part of the ring. For instance, in oak⁸ and elm (D. Brett, personal communication) the width of the early wood is approximately constant, while in most conifers the late-wood width is approximately constant⁴. Early wood and late wood generally have different isotopic composition. The cellulose analyses of Epstein and Yapp⁵ and Wilson and Grinsted⁴ both show differences of up to 50‰ in δD . The latter authors show lighter isotopic values in the early wood which they attribute to temperature-dependent fractionation effects. Epstein and Yapp⁵ disagree with this interpretation. Their analyses show that early-wood isotopic values may be either lighter or heavier than those of the late-wood depending on the location of the tree, and their work suggests that late-wood is isotopically lighter (for Douglas Fir) in regions where there is winter snow cover.

Epstein and Yapp⁵ note that "... differences in early- and late-wood δD could cause sampling problems...". We elaborate here on one way which such problems might arise, and on their possible implications. Approximate constancy of early- or late-wood width, and isotopic variation across a ring, when considered together, necessitate a relationship between ring width and the isotopic value ($\delta^{18}\text{O}$ or δD) of the whole ring. If E is the early-wood width, L the late-wood and $W (= E+L)$ the total ring width, and if δ_E , δ_L and δ_w are the corresponding mean stable isotope

($\delta^{18}\text{O}$ or δD) values, then

$$\delta_w = \delta_E + (\delta_L - \delta_E) L/W \quad (1)$$

or

$$\delta_w = \delta_L - (\delta_L - \delta_E) E/W \quad (2)$$

These alternative expressions for δ_w arise from the fact that δ_w is a weighted average of δ_E and δ_L . They both contain a term proportional to W^{-1} and thus imply a direct functional dependence of δ_w on W . The sign of the relation between δ_w and W depends on the sign of $\delta_L - \delta_E$ and on whether the tree has relatively constant E or relatively constant L .

As ring width is determined partly by climate (although the relation is often complex⁹), these results imply a dependence of δ_w on climate which would occur even if δ_E and δ_L were constants. Thus, at least a part of any δ_w -climate relationship may be attributable to ring width variations.

Whether this 'ring width effect' contributes significantly to variations in δ_w depends on the magnitude of variations in δ_E , δ_L and either E/W or L/W . For oak, where E is approximately constant and equation (2) is the appropriate expression, Eckstein and Schmidt⁸ give ring width data where E/W varies from 0.23 to 0.63 over the period 1880 to 1969. Since $\delta_L - \delta_E$ may be as high as 50‰ for δD , equation (2) shows that the ring width effect could give δD variations for single whole rings of up to 20‰.

Expected variations in $\delta^{18}\text{O}$ of whole rings due to the ring width effect are difficult to estimate because no suitable early-wood and late-wood isotopic data is available. The values would depend on whether precipitation or temperature-dependent fractionation effects are dominant in controlling tree ring isotopic composition, a subject on which there is considerable disagreement. If precipitation effects dominate then $\delta^{18}\text{O}$ variations of order 2.5‰ could be expected as a result of the ring-width effect. If fractionation effects dominated then even greater variations in $\delta^{18}\text{O}$ could occur.

Gray and Thompson¹ and Libby *et al.*² have found significant correlations between whole ring isotopic values and mean annual temperatures. Their results may be partly due to the ring width effect. Gray and Thompson's¹ data show a $\delta^{18}\text{O}$ range of about 3‰ with lower values corresponding to cooler mean annual temperatures. In their case we expect L to be relatively constant. If $\delta_L - \delta_E < 0$, as suggested by the results of Epstein and Yapp⁵, then δ_w should be lower for narrower rings (see equation (1)), and hence, most probably, for colder years. Since Gray and Thompson use 5-yr means, the magnitude of variations due to the ring-width effect could be as much as 1.5‰.

and could account for a significant part of the variation observed. If $\delta_L - \delta_E > 0$ then the ring-width effect would be in the opposite direction and the variation observed by Gray and Thompson¹ would be even more significant.

The results of Libby *et al.*² are more difficult to interpret. One of their oak samples shows variations in δD and $\delta^{18}O$ of approximately 180‰ and 9‰ respectively (for 30-yr means). This variability is much larger than one would expect from the ring-width effect. As Epstein and Yapp⁶ point out, however, the magnitudes of the variations observed by Libby *et al.*² are much larger than one would expect from precipitation isotope variations (which Libby *et al.*² state to be the dominant control). Such large variability is even more unexpected when one recalls that Libby *et al.*² use 30-yr means. Nevertheless, their results do correlate reasonably well with central England temperature data.

Isotopic data from tree rings are potentially a powerful indicator of past climate. There is, however, considerable disagreement between the opinions of different workers in this field, and many of the results seem to be mutually incompatible. The simple analysis presented here suggests that variations in whole ring isotope data may be significantly influenced by variations in ring width, and that such isotope data need not be an independent climate indicator. This additional complicating factor may help to explain some of the incompatibilities. We suggest that a comparison between ring width and isotopic variations should be a first step in any analysis of whole ring isotopic data, whether the data comes from whole wood or chemically more specific isotope measurements.

WILSON REPLIES—Wigley, Gray and Kelly make the valid point that isotopic measurements on whole wood may give results which merely reflect the ring width. One aspect of the problem was discussed by Wilson and Grinsted¹ who pointed out that whole wood contains a mixture of lignin and cellulose which have different isotope compositions. Since

early and late wood can have different lignin to cellulose ratios, isotopic measurements on whole wood may merely reflect the ratio of late wood to early wood which may in turn be a simple reflection of ring width. Wilson and Grinsted suggested that this and other problems could be avoided if isotope dendroclimatologists measured only pure cellulose or pure lignin.

The comments of Wigley *et al.* on the climatic interpretation of the isotopic measurements on tree rings and the relationship of these to past climate involve the fundamental principles on which isotope dendroclimatology is based. Much of the controversy in this field stems from certain misconceptions of the aims of isotope dendroclimatology and the basic plant physiology involved.

Isotopic dendroclimatology studies face two problems. First, at what times of the year is the material that is ultimately formed into wood components fixed from the atmosphere? And second, how does the isotopic composition of a wood component such as cellulose vary with changing climate?

A conifer manufactures photosynthates at all times of the year except when climatic conditions are unsuitable, due for example to low temperatures or drought stress. These photosynthates are stored for short or extended periods before they are laid down as wood. Most conifers (*Pinus radiata* is one of the exceptions) lay down wood only during a brief period of the year. The actual period of wood deposition is not controlled by net photosynthesis but is under hormone control, the production of hormones being controlled principally by day length and to a lesser extent by temperature. For example, in trees suffering from drought stress wood can be laid down during periods when net photosynthesis is negative².

The above considerations apply to any isotopic work on trees. But in the case of isotopic work on oxygen and hydrogen another factor is important. The isotopic composition of rain or snow depends on many factors including the temperature history of the air masses which bring the precipitation to an area³. This is not the end of the problem, however. Once the water is taken into the tree transpiration processes in the leaves can cause very large fractionations particularly in arid environments⁴.

Wigley *et al.* state that “early wood and late wood generally have different isotopic composition”. Leaving aside the point, discussed above, that early and late wood generally have different D/H ratios because they are a variable mixture of more than one compound each with its own isotopic composition. Late-wood cellulose and early-wood cellulose generally have different isotope composition because they represent material fixed from the atmosphere at different

times of the year and hence in different climatic conditions. For example in New Zealand *Pinus radiata* early wood is laid down in the spring and summer and late wood in the winter, that is, early wood is laid down at a warmer time than the late wood. On Mt Lemon, Arizona, *Pinus ponderosa* lays down early wood in the spring and late wood in the summer⁵. That is, early wood is laid down at the colder time than the late wood. The important point is that the isotopic composition is determined by the climate at the time the carbohydrate was fixed from the atmosphere and not whether it is early or late wood that is being formed.

Isotope dendroclimatology can never be expected to produce a mean annual temperature curve as might be produced by a meteorological observer or from measurements of speleothems⁵. It will only produce a curve representative of some period of the year for example ‘a spring and early summer’ temperature curve. Different trees may fix from the atmosphere the carbohydrate ultimately formed into wood at different times of the year and hence record climate at different periods of the year. Obviously a deciduous stress such as an oak growing in New Zealand only carries out photosynthesis in the spring and summer, whereas at the same site a conifer such as *Pinus radiata* can fix material from the atmosphere all times of the year. Thus the wealth of palaeoclimatic data recorded in the isotopic ratios of the constituents of tree rings and the superb time base provided by dendrochronology makes the potential of isotopic dendroclimatology very great indeed.

GRAY AND THOMPSON REPLY—The ‘ring width effect’ discussed by Wigley *et al.* is relevant in two regards to our findings of significant correlation between $\delta^{18}O$ values in cellulose and mean annual temperatures¹. First, as stated by Wigley *et al.*, there is a possibility that an appreciable fraction of the variation in the $\delta^{18}O$ values may be due to varying proportions of early and late wood in the tree rings used for analysis. Second, the possibility exists of a sampling error being introduced when a 5-yr group of rings is analysed.

To evaluate the first effect we have made measurements of late-wood width (*L*), early-wood width (*E*), and total ring

width (W) for the entire section of tree used for production of the climate curve¹. Values of L/W ranged from 0.05 for the largest value of W to 0.32 for the smallest W . Further, $^{18}\text{O}/^{16}\text{O}$ isotopic analyses were carried out on early and late wood from a number of selected rings from the tree. (These were necessarily rings having larger values for W due to difficulties associated with the sampling of narrow rings and insufficiency of material for analysis.) The range of values found for the difference in isotopic composition between early and late wood ($\delta E - \delta L$) was found to be 0.5 to 0.8‰.

Thus using equation (1) as stated by Wigley *et al.* with values of $\delta L - \delta E = -0.8$ ‰ and $L/W = 0.32$ the maximum variation in δW due to the term dependent on total ring width is found to be 0.26‰. Thus the maximum contribution to the variation is estimated at somewhat less than 10% of the total variation observed (3‰) in a 100-yr-old tree. Furthermore, by taking 5-yr groups of rings this effect will tend to be minimised since the tree in question contained few narrow rings and the effect is much less significant for wider rings (L/W of the order 0.05). In general, therefore, we expect the effect to be considerably less than the 10% suggested above.

The measured values of tree ring width (W) for the Edmonton spruce, after growth curve corrections were made, show little or no correlation with mean annual temperatures. We conclude that in this case, the contribution of ring-width effects to variation in $\delta^{18}\text{O}$ of the cellulose is minimal. This finding, however, does not detract from the potential significance of the effect for other trees in other climate zones. Care should be taken to select trees which are 'complacent', that is, those with ring widths showing little annual variation. (This is in contrast to the requirements of those establishing climate curves from ring-width measurements².) The second possible effect of ring-width variation, that of introduction of a sampling error, arises because, when sampling 5-yr groups of rings¹, no attempt was made to normalise the amount of wood contributed by each of the rings to the material subsequently analysed. When calculating mean annual temperatures for each 5-yr period, however, an arithmetic mean was used, implying equal contribution from each ring, and hence implying equal ring width throughout the 5-yr group. To estimate the error introduced by this procedure, we measured total ring widths for the entire tree. Using mean annual temperature (T) from climate records we calculated the expected isotopic composition of the cellulose in each ring using the relation $\delta^{18}\text{O} = 1.3T + 20.5$ (‰) (ref. 1). The mean $\delta^{18}\text{O}$ for each 5-yr group of rings was then calculated first using

Table 1 Comparison of ring-width weighted mean, non-weighted mean and measured $\delta^{18}\text{O}$ values for cellulose extracted from 5-yr groups of tree rings

Period	$\delta^{18}\text{O}$ (‰) weighted mean	$\delta^{18}\text{O}$ (‰) unweighted mean	$\delta^{18}\text{O}$ (‰) measured
1894-99	23.4	23.5	23.4
1900-04	24.2	24.4	24.1
1905-09	24.7	24.6	24.7
1910-14	24.6	24.6	24.7
1915-19	24.0	24.0	24.1
1920-24	23.8	24.0	24.2
1925-29	23.7	23.5	23.6
1930-34	24.6	24.7	24.7
1935-39	23.2	23.3	22.9
1940-44	24.9	24.6	24.5
1945-49	23.8	23.7	23.3
1950-54	23.7	23.3	23.3
1955-59	24.4	24.5	24.5
1960-64	25.1	25.3	25.2
1965-68	23.5	23.7	24.0

the ring-width data as a means of weighting the $\delta^{18}\text{O}$ contribution of each ring and second, assuming equal contributions for each ring in a given 5-yr group. The calculated weighted and unweighted means, together with measured values are shown in Table 1. The largest difference between weighted and unweighted calculated value is 0.4‰, approximately twice the estimated precision of the measured data (± 0.2 ‰). It seems that errors introduced elsewhere in the procedures used, are usually equal to or greater than those due to sampling errors. It should be pointed out, however, that trees showing marked variability of ring width with climate may well present sampling problems of this kind.

LIBBY AND PANDOLFI REPLY—Pandolfi has shown that isotope variations in tree rings are correlated with climate variations local to the trees. Wigley *et al.* speculate that isotope variations in tree rings may be correlated with ring widths. Then if they are correct, it must follow that ring widths are correlated with climate.

We consider that the master chronologies of ring widths from the European tree laboratories will not correlate with local climate variations. We found no correlation between isotope measurements for a German oak and B. Huber's master oak ring chronology.

Amide nitrogen is unlikely to be a proton acceptor

In their article on the mechanism of catalysis of acid proteases and extended to proteases generally, James *et al.*¹ make several statements to the effect that a tyrosine donates its proton to the amide nitrogen of the scissile bond in a peptide substrate. This mechanistic idea is similar to that suggested for hydrolysis of peptide substrates by carboxypeptidase^{2,3}. But the peptide nitrogen is not the basic site in an amide bond and cannot accept a proton, a hydrogen bond, or a metal ion in the ground state of an enzyme-substrate complex⁴. This restriction holds with even more force when the amide carbonyl oxygen interacts with a proton or a metal ion, as is thought to be the case with carboxypeptidase.

There are many data to support the view that the basic site in an amide bond is the carbonyl oxygen so that either a proton^{5,6} or a metal ion^{7,8} associates at that atom. These conclusions are supported by theoretical calculations which indicate a strong preference for protonation of amides at the carbonyl oxygen^{9,10}. Unless there is enormous strain associated with substrate binding, the earliest stage in a hydrolysis mechanism during which an amide nitrogen may become a proton, hydrogen bond, or metal ion acceptor is concerted with nucleophilic attack at the amide carbon which results in both the carbon and nitrogen of the amide bond taking on tetrahedral character⁴. At this point the nitrogen has lost its amide character and has become an amine nitrogen. This principle seems to have been accepted in a recent discussion of the mechanism of thermolysin which is thought to be similar to that of carboxypeptidase¹¹. Though the authors of the acid protease paper¹ may feel that they did not violate this principle in their own minds, their statements coupled with proposed mechanisms in the literature cited are apt to mislead many readers.

BIOLOGICAL NITROGEN FIXATION IN FARMING SYSTEMS OF THE TROPICS

edited by **A. Ayanaba**, *International Institute of Tropical Agriculture, Ibadan, Nigeria*, and **P. J. Dart**, *International Crops Research Institute for the Semi-Arid Tropics, Hyderabad, India*.

This volume is based on a Symposium held at the International Institute of Tropical Agriculture, in Ibadan, Nigeria, in October 1975. The Symposium's objectives included: an appraisal of the most recent studies relating to microbiological nitrogen fixation in tropical soils; consideration of methods of improving management of soils and crops in tropical farming systems to increase biological nitrogen fixation; exploration of ways of concurrently improving both legumes and other hosts and their symbionts to enhance nitrogen fixation; and recommendations on the research needed and methods of collaboration.

THE CHEMISTRY OF CYANATES AND THEIR THIO DERIVATIVES

edited by **S. Patil**, *Department of Organic Chemistry, The Hebrew University, Jerusalem, Israel*.

The Series 'The Chemistry of the Functional Groups' is planned to cover in each volume all aspects of the chemistry of one of the important functional groups in organic chemistry, in this case cyanates and their thio derivatives. The emphasis is laid on the functional group treated and on the effects which it exerts on the chemical and physical properties, primarily in the immediate vicinity of the group in question, and secondly on the behaviour of the whole molecule. The authors concentrate on important recent developments and on material which has not been well covered in other literature. (Series: The Chemistry of the Functional Groups) December 1977

MATHEMATICAL AND BIOLOGICAL INTERRELATIONS

by **B. A. C. Dudley**, *Department of Education, The University of Keele, Staffordshire*.

The purpose of this book is to illustrate the interplay between mathematics and biology. A comprehensive mathematical background is not assumed as the author feels that both biology teachers and students appreciate a more basic approach to the discipline. The book begins with alternative presentations of simple biological data and ends with the interpretation of exponential growth and decay. Relationships that underly apparently different phenomena, both biological and mathematical, are discussed and the author is particularly concerned to show that information helpful to a biologist can be derived from the mathematics of a biological system.

ORGANIC REACTION MECHANISMS 1976

edited by **A. R. Butler**, *Department of Chemistry, University of St. Andrews*, and **M. J. Perkins**, *Department of Chemistry, Chelsea College, University of London*.

This twelfth volume, continuing the pattern now established for the series, surveys work on organic reaction mechanisms appearing in the literature dated December 1975 to November 1976. The aim has, as before, been to provide a concise and comprehensive coverage of work published in the period under review; where, at the time of writing, any particular results seemed of outstanding significance, these are described and discussed. The remainder are listed.

CONSERVATION AND AGRICULTURE

edited by **Joan Davidson**, *Lecturer in Rural Planning, Gloucestershire College of Art and Design, Cheltenham*, and **R. Lloyd**, *Principal Research Officer, Countryside Commission*.

This book sets out some of the consequences of recent and further developments in agriculture for the landscapes and major ecosystems of the farmed countryside; but it is also concerned with the means by which wildlife and landscape values might be safeguarded. The authors have tried to be realistic, suggesting where the ecological effects of modern agriculture matter most, and exploring those means of conservation which seem to be economically and politically feasible at the present time. Throughout, the aim has been to bridge some of the gaps in information and understanding that exist between the many different groups with a stake in rural land management, including farmers and their advisers, planners, ecologists and conservationists.

MARINE ECOLOGY Vol. 3, Parts 2 & 3

edited by **O. Kinne**, *Biologische Anstalt Helgoland, Hamburg*.

Ecology comprises studies of organisms in relation to their environment, abiotic and biotic. Marine ecology deals with the vast multiplicity of organisms living in oceans and coastal waters. This treatise attempts to cover all major aspects of marine ecology. It consists of 5 volumes. Volume III, Cultivation, reviews the information which has accumulated on our capacity for supporting marine micro-organisms, plants and animals under environmental and nutritive conditions which are, to a considerable degree, controlled. (Marine Ecology Series)

Contents: Part 2: Cultivation of Animals — Research Cultivation (O. Kinne). Part 3: Axenic Cultivation (L. Provasoli); Commercial Cultivation (Aqua-culture) (O. Kinne and H. Rosenthal); Multispecies Cultures and Microcosms (M. Lerandowsky); Chemical Contamination of Culture Media: Assessment, Avoidance and Control (M. Bernard).

American Natural History

Jack Major

Natural History in America. By Wayne Hanley. Pp.xiii+334. (Harper and Row: London; Quadrangle/New York Times Books: New York, 1977.) £8.95; Fl.40.65; \$14.95.

THE author compiles and discusses excerpts from the record of natural history observations during settlement of the US over the past two centuries. Ornithology is emphasised. Colour plates of paintings made by the eighteenth- to nineteenth-century naturalists are included. Unfortunately, the book has no index, nor reference list. Hanley's method is to quote passages from the early naturalists' published work and to relate them to then contemporary events in the biological sciences at large. Thus, Linnaeus and his emissary Peter Kalm, as well as Darwin's work, are very much present in early American natural history. The author introduces his book modestly: "This is not a profound volume. It is essentially a collection of readable passages selected from the writings of great American naturalists" (page xi). Too modestly. The events and thoughts described and quoted have acquired a profundity in our time when America has used up so much of its bountiful inheritance and when so many are so concerned that some of our wonderful natural heritage be passed on to future generations.

Modern naturalists will be deeply impressed, also, by young Meriwether Lewis setting forth on his extended (1804-1806) field trip into the wilderness bearing a hand-written, open letter of credit from President Jefferson authorising unlimited funds on the credit of the US Government. The Indian woman, Sacajawea, who guided him through the Rocky Mountains was of more help.

The book opens with a chapter, "In the Beginning: Catesby", on "an exception to the general rule of incompetence or worse among early eighteenth-century naturalists"—Mark Catesby's hand-coloured, illustrated *Natural History of Carolina, Florida and the Bahama Islands* of 1730-1748. His stiff but accurate paintings are followed by discussion of John and William Bartram, collectors of plants and ornithologists; of Alexander Wilson, with

Gray

his colour-illustrated, nine-volume *American Ornithology*; and climaxed by Audobon's magnificent paintings and vivid writings and his collaboration with the mammalogist John Bachman. The western part of the present US was almost unknown to these naturalists, and one gets the impression they regarded its biological riches from the standpoint of the Boston dowager who described her route to San Francisco, over 4,000 km distance, by way of Newton, a suburb of Boston. But they were fully occupied with the area east of the Mississippi River from Labrador south to Florida, and the modern naturalist can only appreciate and envy their discoveries.

Lewis and Clark explored westward from St Louis, Missouri, to the Pacific. They are given a chapter. Hanley emphasises their written interest in the grizzly bear and Indian horses, almost to the exclusion of the other myriad new forms of plant and animal life they encountered on their epic journey. Horses are of obvious interest to anyone on a walk from St Louis to the mouth of the Columbia River. And anyone afoot, armed or unarmed, who has seen a grizzly moving ponderously but so fluidly about its own business and then throw up its head to stare at the intruder, will sympathise with Lewis and Clark's deep interest.

Although Hanley's book has in its title *America*, Canadian contributions are absent. The voyageurs who performed miracles of physical labour and daring in penetrating America toward the Pacific, and the Hudson Bay and North-West Company factors who em-

Agassiz

ployed them seem to have written little on the Natural History of these virgin lands, for reasons of illiteracy or business priorities. But Sir Alexander Mackenzie's journals describing his explorations from Lake Athabasca to the Arctic Ocean (1789) and then to the Pacific at Bella Coola (1792-1793) are not devoid of Natural History observations. True, he noted birch and spruce because they could furnish bark and gum to repair his canoe, various shrubs because their berries were edible, devils club (*Oplopanax horridum*) because it hindered his progress; but transportation and food of necessity were his primary interests. And he did hesitate on his perilous return journey to measure one of the giant cedars (*Thuja plicata*) which he noted characterised the magnificent coniferous forest of the Pacific slope.

But Hanley has plenty of material in the US alone. Thomas Nuttall collected plants throughout much of the US, wrote a catalogue of American plants, a botanical textbook, a bird manual, spent 11 years at Harvard University, and ended up on an inherited estate in England. Thomas Say, on the other hand, seems to have been totally disinterested in money, but he was interested in collecting, travelling, and he advanced Natural History knowledge, uniquely in entomology and conchology.

N. M. Hentz, too, was eccentrically interested in less well-known organisms, spiders in his case. The climax comes with Rafinesque. It was a taxonomic climax, only exceeded by the collections of the exploring expedition

around the world under Lieutenant Charles Wilkes, who not only went to Antarctica but whose shore parties contributed to our knowledge of Mount Shasta in northern California. Hanley also devotes a chapter to the whalers, including the novelist Herman Melville who was a crew member in the bloody business "until he jumped ship at Marquesas Island in July, 1842, preferring to live among cannibals".

And finally comes the first writer and naturalist in Hanley's collection who looked at nature as a whole, with sympathy. Did Thoreau's words exert much influence? Probably not, but we are discovering them anew. He is a charming prophet.

In the following chapter, Agassiz and Asa Gray differed over Darwin's ideas without adding much to them, and they gave Harvard an early taste of dissension among its faculty.

Academic nastiness accompanies Cope and Marsh in their disputes over priority of publication, ownership of specimens, money, and anything else handy one feels. Living reptiles and amphibians found a specialist in J. E. Holbrook.

Elliott Coues was an improbable cavalryman, briefly a member of the mystical Theosophical Society of India, a superb ornithologist whose description and advocacy of bird identification using a shotgun is illuminating. Hanley progresses from the "I do not protect birds, I kill them" school of ornithology to preservationist attempts to stop some of the slaughter of wildlife. First, to stop commercial use of bird skins to decorate women and, later, to save enough big game so hunting could continue. Protagonists of the latter crusade included W. T. Hornaday and Theodore Roosevelt. In the western US, John Muir took up some of the same themes Thoreau had broached in the east. He, too, was ahead of his time in suggesting that not every last resource should be used up by the generation then in propertied possession.

Popularisers of Natural History such as John Burroughs and Ernest Thompson Seton aroused interest in the life histories of mammals in general. If Seton was an egotist, he also had much field experience and was a competent mammalogist. Burroughs deliberately kept the observer (himself) in the forefront of his observations and descriptions, to the detriment of both. Louis Agassiz Fuertes seems to have been a paragon, not only as a painter of birds but as a fine field companion.

An appreciation of the place of predators in the scheme of nature began to appear only with C. Hart Merriam, working within the government. Aldo Leopold progressed to this view, wrote

a textbook which made wildlife management a field of study, and suggested a philosophy of land use in consonance with Thoreau's ideas. But their ideas are still ahead of the economic and commercial mores of our time. Our time is one of continuing pollution of our environment, and Rachel Carson has the last chilling word.

Each person will have his own list of people, quotes, ideas, landmarks, interactions left out of Hanley's little book. The early geologists such as Gilbert, Dutton, Powell, Russell in the western US, and the early ecologists such as

Forbes, Clements, Cowles, Harper, Kearney, Sears, Weaver would be mine. But even if the scope of American Natural History over the past 200 years seems occasionally to approach a Boston ornithologist-dowager's view, Hanley has produced a wonderfully readable and useful account. I hope it will stimulate readers to learn more of the background of our present ecological crises and the science that works toward their solution. □

Jack Major is Professor of Botany at the University of California at Davis.

Running a bird reserve

Minsmere: Portrait of a Bird Reserve. By Herbert Axell and Eric Hosking. Pp. 256. (Hutchinson: London, 1977.) £7.50.

BASICALLY, as its title suggests, this is the story of the setting up and running of a reserve. It is also, however, rather more than that. Minsmere, on the Suffolk coast, is one of the largest and most famous reserves run by the Royal Society for the Protection of Birds (RSPB), and the author was the warden of the reserve for 17 years and was responsible for many of the innovations carried out there.

Before the last war, Minsmere was a low-lying area of farmland, vulnerable to flooding by the sea. In June 1940, it was intentionally flooded as part of Britain's coastal defences against possible invasion by the Germans. In short, the birds approved and by the end of the war a number of rare species were established there. In 1947, the RSPB acquired a lease of the new marshes, together with adjacent areas of heath and woodland.

The book describes the birds of all the Minsmere habitats, giving particular prominence to those that are rare elsewhere in Britain. There are four of these; three—the Bittern, Marsh Harrier and Bearded Tit—are reed-bed birds. Once common over wide areas of Britain, these species have slowly dwindled with the general drainage, particularly of the Fens. The Marsh Harrier and Bittern are reduced to very small numbers in the UK at present, indeed at one stage Marsh Harriers bred nowhere apart from Minsmere. It is one of those wry complexities which nature all too frequently sets for conservationists, that anxious parent Bitterns occasionally satisfy the needs of their clamouring young with baby Marsh Harriers from an adjacent nest. The Bearded Tit is more numerous than the other species and at the

moment more widespread. It was, however, once scarcer and at that time Minsmere was the essential base from which, at a later date, the other colonists spread out.

Maintaining habitat in the stage at which the birds need it, is not just a matter of sitting about; it needs active management. This is especially the case with the fast growing reed-beds. The author not only discusses his day-to-day problems, but also describes new developments which he initiated. Over a series of winters (so the breeding birds would not be disturbed), bulldozers gradually made a series of shallow pools, now famous as "The Scrape". To these, and their gravel-covered islands, birds came in large numbers. Among these were the terns, whose nesting areas along the beach were almost ceaselessly disturbed by people; and waders, whose shallow feeding areas are now so scarce. The other bird to approve of these moves was the Avocet—the fourth species to merit a chapter to itself. With only one other nesting colony in Britain (on Havergate, another RSPB reserve), this was a welcome development.

Perhaps one of the points that emerges from this book is how successful a man-made marsh can be. One cannot, at will, reproduce a mature oakwood, but one can reproduce quite quickly many of the necessary features of a marsh. As drainage relentlessly goes on, perhaps more organisations could be persuaded to find low-lying land which could be used to make amends, albeit in a small way, for some of the losses.

The book is beautifully and profusely illustrated, mostly by Eric Hosking's own photographs. My only criticism is that some of the colour photographs are reproduced at six to a page, and the small size does not permit one to fully appreciate their quality.

C. M. Perrins

C. M. Perrins is Director of the Edward Grey Institute of Field Ornithology, University of Oxford, UK.

New liquid scintillation review

Sample preparation in liquid scintillation counting by C.T. Peng.

A recent title in our series of Review Booklets on subjects of interest to users of radioisotopes. It includes a brief account of liquid scintillation processes, and a review of the various aspects of sample preparation.

The booklet will bring the most pertinent information on sample preparation to new users and more recent developments to those already familiar with the technique.

Steady-State Enzyme Kinetics

**Stanley
Ainsworth**

Identifies the basic ideas of the subject for the graduate and advanced undergraduate student, and familiarises the reader with them so that they may then be applied to any problem likely to be encountered. Although it cannot altogether avoid mathematical presentation, almost all the equations used require only an elementary acquaintance with algebraic manipulation. Moreover the arguments themselves are presented as fully as possible to enable the reader to progress easily from each stage to the next.

Butterfly origin

The British Butterflies: Their Origin and Establishment. By R. L. H. Dennis. Pp. xviii+318. (E. W. Classey: Faringdon, UK, 1977.) £10.

THE message of this book is simple: recent work on the British Pleistocene suggests that all Britain's butterflies must have been exterminated by cold before the amelioration of climate which began 10–15,000 yr ago; no existing populations of butterflies in the British Isles, including various endemic "subspecies", can be older than that. This view contrasts with the earlier ideas of B. P. Beirne and E. B. Ford, who, working with a radically different and now outmoded reconstruction of Pleistocene events, considered that at least some of our butterflies had existed continuously in Britain for 100,000 yr or more. Dennis's book has some subsidiary themes, one being that phenotypic divergence of a butterfly population bears no direct relationship to either its antiquity or total genetic divergence. I agree with both of these conclusions.

Dennis's treatment of the subject is based on a wide reading of the work on the Pleistocene, local literature pertaining to the distribution and ecology of British butterflies, and an eclectic selection of genetical texts. Two extremely relevant areas of work are completely ignored: MacArthur–Wilson island biogeography theory, aspects of which Dennis apparently rediscovers for himself, and Paul Ehrlich's school of work on *Euphydryas* colony structure. He does refer once to the classic paper of Ehrlich and Raven on butterfly and plant coevolution. In doing so, he misspells Erlich (*sic*), gives the wrong publication date, and apparently misunderstands the particular ideas of biochemical coevolution involved. Further, in discussing phenotypic divergence, antiquity and evolutionary rates, Dennis makes no reference to work on rates of protein evolution.

If the essential message of the book is simple, and key areas of the literature have been ignored, why does Dennis's main text span 270 close-set pages? Because he frequently uses whole sentences where one word (or even none!) would suffice. He is at pains at every point to indicate that he has thought of every possibility. He attacks the same problems again and again, using the very few lines of evidence open to him. As a result, instead of being a delightful natural history detective story, the book is bewildering. Alternative hypotheses are not presented and dealt with in a logical way, step by step. Instead, we are fed with an unending torrent of jargon-laden fact, theory and specula-

tion, leaving the reader in a state of dizzying confusion. Beneath this, many of Dennis's ideas are sound, and one gets an impression of tremendous enthusiasm. If so, it is unfortunate that the book has been published in its present, clearly unedited state, because both the author and his intended audience are the losers.

In short, although it will have some value as a reference source, and for Dennis's original contributions on the analysis of distribution, I cannot recommend this as a good book. I looked forward with keen anticipation to reading it, which is perhaps partly why I find it disappointing. But it is the language which really spoils it. For example, on p243 we are told that "Bearing in mind the reticulate control pathways of atmospheric inputs

into local ecosystems, and the original and ultimate dependence of contemporary environments on atmospheric influences, though modified by the interaction of living and non-living components, and thus, in the attempt, to avoid recourse to simplistic determinism, it is suggested that the increasing assumption of oceanic conditions to the north and west of Britain has resulted in a primary structure of selection gradients." Such gems of egregious obfuscation abound throughout the whole work. Only the dedicated will probe below this forbidding mask.

R. I. Vane-Wright is Head of the Butterfly Section at the British Museum (Natural History).

Chemical dynamics

Dynamics of Molecular Collisions. Parts A and B. Modern Theoretical Chemistry. Vol. 1. Pp. 318. \$39.50. Vol. 2. Pp. 380. \$47.40. Edited by W. H. Miller. (Plenum: New York and London, 1977).

IN the past fifteen years, there has been much progress in the field now known as chemical dynamics. The development of the crossed-molecular-beam technique provided a means of studying chemical reactions in more detail, and many new and powerful experimental techniques are now being used in this area. It is now reasonable to ask an ultimate question in kinetics: what is the cross-section for scattering at a particular angle from each state *i* of species *A* to every state *f* of a product *B* at any relative energy? This experimental activity has led chemists into scattering theory; previously, this had been a province of physics. New theoretical techniques and models have been developed by chemists for handling molecular collisions, and some of these are now finding applications in certain areas of physics.

These first two volumes in the series *Modern Theoretical Chemistry* contain thirteen chapters, each by a different author, on theoretical techniques that are appropriate for describing chemical dynamics. The first, by W. A. Lester, Jr, is on the *N* coupled-channel problem. The author likens coupled-channel methods to *ab initio* computations of molecular properties, for they provide a source of reliable data in cases where experiments may be difficult and they serve as a test of approximate methods. The second, by H. Rabitz, is devoted to effective Hamiltonians; it describes various means of reducing the number of rotational

channels that need to be considered explicitly. There is a chapter by D. A. Micha on the use of optical potentials in molecular collisions—their name comes from the analogy between the wave-mechanical aspects of molecular collisions and electromagnetic propagation in an inhomogeneous medium with a complex index of refraction. There is a chapter on vibrational energy transfer by H. K. Shin, and one on the scattering of atoms and molecules from solid surfaces by G. Wolken, Jr. The final chapter in Part A is a very clear account of the theory of non-radiative processes by W. Siebrand.

Part B contains articles on classical and semi-classical methods. It begins with a chapter on classical trajectory methods by R. N. Porter and L. M. Raff. The second chapter, by P. J. Kuntz, is an excellent account of the effect of features of the potential energy surface on molecular collisions. The third chapter, by W. L. Hase, is concerned with the dynamics of unimolecular reactions, and in particular with the RRKM theory. M. S. Child contributes a useful chapter on semi-classical methods and J. C. Tully writes on non-adiabatic processes in molecular collisions. The sixth chapter, by P. Pechukas, is on statistical approximations in collision theory, that is, on the transition-state theory. The final chapter, by R. D. Levine and R. B. Bernstein, is on the thermodynamic approach to collisions; it makes use of information theory.

The topics have been well selected and the authors are known for their work in the field. These two volumes will be very useful to research workers entering the field.

A. D. Buckingham

A. D. Buckingham is Professor of Chemistry at the University of Cambridge, UK.

Mechanisms of animal locomotion

Mechanics and Energetics of Animal Locomotion. Edited by R. McN. Alexander and G. Goldspink. Pp. 346 (Chapman and Hall: London, 1977.) £15.

FOR nearly 30 years from the early 1930s, Sir James Gray and his colleagues at Cambridge published a steady stream of papers analysing how animals move in locomotion. There were distinguished earlier and contemporary contributions by others, but Gray set the foundation for the modern development of the subject. His body of work was largely concerned with the kinetics of locomotion and explained how the movements of most groups of animals exerted appropriate thrusts against the environment and produced locomotion. Some progress was made with explaining the nervous coordination of locomotory movements in a few animals and the energetics of locomotion, but there was little advance in the formidably difficult subjects of the aerodynamics or hydrodynamics of animal movement through fluids. During this period, studies of animal locomotion had their firmest links with comparative anatomy, exemplified in the magnificent and detailed functional analysis of the locomotory musculature of arthropods by Sydney Manton (whose book on arthropod locomotion will be published later this year). The physiological dimensions remained relatively underdeveloped alongside this.

The past 20 years have seen a remarkable change in the subject. Previously, animal locomotion was a specialised, rather isolated topic which could be safely ignored by most zoologists. Now, it has become a coherent, mainstream subject drawing together a great variety of scientific knowledge and expertise. As the preface to this volume says with some justice: "it seems a good time to produce a book".

This is an exceptionally good one. It deals with the entire subject of animal locomotion from muscle physiology and nervous coordination to energetics and the kinetics and dynamics of locomotion. Nearly all the topics discussed are difficult for the non-specialist to penetrate, but here they are introduced in an unusually clear, economical and intelligible style. Every concession is made to the reader, and an undergraduate with no previous knowledge of any of these subjects could read this book without much difficulty and with enormous profit. Inevitably, this has led to some simplification and loss of

detail. There is a good chapter on co-ordination of invertebrate locomotion by Delcomyn and another, shorter, chapter on crawling and burrowing in soft-bodied invertebrates by Trueman and Jones. Otherwise, invertebrates (arthropods in particular) get rather brief treatment and the main emphasis is on the locomotion of vertebrates. Viewed as a whole, however, the book provides an excellent account of the current state of our understanding of the mechanisms of animal locomotion.

The book starts with chapters on the design, mechanics and energetics of muscles involved in locomotion, the coordination of invertebrate and vertebrate locomotion, the energy cost, and then concludes with chapters on terrestrial locomotion, crawling and bur-

rowing, swimming, flying and, finally, the locomotion of Protozoa and single cells. There are good bibliographies at the end of each chapter and the book is well illustrated and produced. The editors are to be congratulated on having recruited a very authoritative team of nine authors and, still more, for having achieved a remarkable consistency of style and uniformity of treatment throughout the book. This is not a compendium of separate, contributed articles as so often happens with multi-author volumes; it has rather been welded into a coherent book.

R. B. Clark

R. B. Clark is Professor of Zoology at the University of Newcastle upon Tyne, UK.

Cell division

Mechanisms and Control of Cell Division. Edited by Thomas L. Rost and Ernest M. Gifford. Pp. vii+387 (Dowden, Hutchinson and Ross: Stroudsburg, Pennsylvania; Halsted/Wiley: New York and Chichester, UK, 1977.) \$31.50; £18.75.

BIOLOGY is suffering a proliferation of books, many of which are simply new combinations of material that has already seen printer's ink at least one and often more times. Sometimes this is justified; a comprehensive well-planned collection can usefully summarise and occasionally illuminate a particular field. This expensive little collection, though containing some new material, does neither. The editors describe it as a "compendium of several areas of cell cycle research, especially those dealing with plants. Some . . . reviews . . . new ideas and the results of recent research" for "researchers and advanced students interested in cell behaviour". The precise purpose is not stated. Was it perhaps simply to market another book? Certainly, the title has all the keywords for the big sell.

In the chapter summarising their elegant dissections of the cell cycle in *Allium* meristems, Giménez-Martin *et al.* point out that in the strict sense "cell division" refers only to mitosis and cytokinesis but is often loosely applied to all processes of proliferation including interphase growth. In making their selection, the editors seem to have been confused about which sense to follow. As a result the collection, which contains some good material, is a hotch-potch.

Gurley *et al.* review their work on biochemical events associated with proliferation of an animal cell-line in culture, Douvas and Bonner re-describe the isolation of contractile proteins from liver chromatin. There follow two interesting reviews of plant hormones and cell proliferation, a list of factors affecting plant cell cycles, a catalogue of structural changes in plant and animal nuclei during replication, two reports on plant cell ultrastructure during mitosis and one of several current hypotheses purporting to explain chromosome movement. The penultimate article is part 1 of an anatomy of cell division in euglenoid algae and the ultimate a detailed description of *all* the stages of mitosis and meiosis and their variations in basidiomycotinal fungi. Several contributions have the prose density of a Patrick White novel.

Despite its dynamic title the collection contains much that is purely descriptive. Being diverse, it lacks the connecting thread that makes a cover-to-cover reading easy or inspiring. Being thinly spread, it fails as a definitive reference source.

The book is strongly bound, but paperbacking would have sufficed and might have halved the price. There is a subject but no author index, nor notes on contributors other than the editors. Many of the numerous electron-micrographs are reproduced with a fuzziness that seriously obscures fine detail. The layout is wasteful: a line diagram of six microtubules occupies a page, as do many other diagrams originally published at a quarter of the size.

L. Martin

L. Martin is a member of the Hormone Physiology Department at the Imperial Cancer Research Fund Laboratories, London, UK.

THE OPEN UNIVERSITY

Faculty of Science

ANIMAL TECHNICIAN

£2,689 — £3,087
(under review)

Applications are invited for the post of Animal Technician in the Faculty of Science, tenable from January 1, 1978, or as soon as possible thereafter. The Animal House services the research and training activities of the Biology Discipline and has breeding colonies of rats, mice and marmosets and holding facilities for rabbits, chicks, fish and amphibia.

The successful candidate, male or female, will assist the Senior Animal Technician in the day to day running of the Animal Unit. Candidates should possess AIAT or equivalent qualifications and have at least six years' experience.

The person appointed will be expected to live within 20 miles of the University. We do offer assistance with removal expenses to make this possible. There is a wide variety of corporation and private housing, and we have an Accommodation Officer to advise and help new appointees. The University offers generous holidays and excellent social and sporting facilities.

Further particulars and application forms are available, by postcard request please, from The Personnel Manager (AT 1), The Open University, P.O. Box 75, Walton Hall, Milton Keynes MK7 6AL, or by telephone from Milton Keynes 63868. Closing date for applications: January 18, 1978. 884(A)

UNIVERSITY OF NOTTINGHAM CANCER RESEARCH CAMPAIGN LABORATORIES

A Grade 3 Laboratory Technician is required in the Cancer Research Campaign Laboratories. This post is funded by a research grant and is offered initially for a period of 2 years. The duties will involve assistance mainly with tissue culture and immunological assays in the laboratory. Some assistance with animal research will also be required. Applicants should preferably have a minimum of 3 years experience in this kind of work and possess appropriate qualifications.

Salary in the range of £2,688 to £3,060 per annum.

Applications in writing to the Establishment Officer, University of Nottingham, University Park, Nottingham NG7 2RD giving the names of two referees and quoting Ref. No. CR 2/12/77. 900(A)

appointment of Director (male or female) Brain Metabolism Unit

The Council invites applications for the post of full-time Director at the MRC Brain Metabolism Unit in Edinburgh, following the resignation of Dr Ashcroft to take up the Chair of Psychiatry at Aberdeen. The successful applicant will be a person of high scientific standing (with or without a medical qualification), with an established reputation as an original scientific investigator. The Unit is at present engaged on experimental and clinical research relevant to psychiatry and neurology. The Council wishes the emphasis on the psychiatric interests of the Unit to be maintained. The title and programme of the Unit will be decided by the Council in the light of the research interests of the new Director.

The Unit is mainly housed in purpose-built research accommodation of approximately 4,000 sq ft (nett). A research team of clinical and non-clinical staff is already in post: the size of the Unit will be a matter for discussion between the Director and the Council. The Director will be responsible for maintaining the strong links already existing with the University of Edinburgh.

The salary for a medically-qualified Director, for whom an honorary clinical contract at consultant level will be sought, will be on the MRC clinical scale, equivalent to NHS consultant grade; if an honorary contract is not appropriate, the salary will be within the range for the Council's Special Appointments Grade, which is equivalent to the University professorial range.

MRC

Medical Research Council

Further information may be obtained from Miss R Withnall, 20 Park Crescent, London W1N 4AL. Applications should be submitted to the Secretary of the Council at the same address, not later than 13 February 1978.

THE GOVERNMENT OF THE SYRIAN ARAB REPUBLIC ALEPPO UNIVERSITY

Faculty of Medicine

Invites applicants for the following posts as visiting professors for short periods (minimum 6 weeks) vacant 1977/1978 and 1978/1979.

Internal Medicine: M.R.C.P. or American Board in the following:

- Endocrinology
- Immunology
- Liver Diseases
- Infectious Diseases

Surgery: F.R.C.S. or American Board in the following:

- Anatomy
- Pathology
- Surgical Anatomy
- Surgical Pathology

Paediatrics: M.R.C.P. or American Board, in addition to five years experience.

£660 per month

£230 Accommodation allowance per month

Return tickets for the professor.

Please write for full details to:

The Rector
University of Aleppo
Syrian Arab Republic.

865(A)

ST MARY'S HOSPITAL MEDICAL SCHOOL (University of London)

Paddington, London W2 1PG

POSTDOCTORAL

RESEARCH ASSISTANT

FOR DEPARTMENT OF MEDICINE

Applications are invited for a Senior Research Assistant to work on the regulation of renal blood flow in animals. Project entails the development of techniques for the measurement of blood flow to different regions of the kidney and for the collection of renal lymph. The Medical Unit (Director: Professor W. S. Peart) contains other scientists and doctors working on related projects. Some experience in experimental work with animals required. Candidates should hold a doctorate in one of the Biological Sciences. Post is for 3 years in first instance with salary appropriate to qualifications; it is available on or after February 1, 1978.

Further details obtainable from Dr C. S. Wilcox (Tel: 01-262 1280 Ext. 238). Apply in writing to The School Secretary, St Mary's Medical School from whom application forms should first be obtained.

Closing date for applications January 25, 1978. 888(A)

CSIRO AUSTRALIA RESEARCH SCIENTIST

(2 Positions)

DIVISION OF ANIMAL PRODUCTION

ROCKHAMPTON, QUEENSLAND, PROSPECT, N.S.W.

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,300 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELDS: 1. REPRODUCTIVE PHYSIOLOGY

2. ANIMAL BREEDING

GENERAL: The Division has six broadly-based programs of research on tropical animal production, strategic nutrition of livestock, skin and fleece biology, mineral requirements for livestock production, improvement in reproductive efficiency, and animal breeding and genetics, and has laboratories in Rockhampton, Armidale, Sydney and Perth.

1. REFERENCE NUMBER 245/675

FIELD: REPRODUCTIVE PHYSIOLOGY

LOCATION: ROCKHAMPTON, QLD

DUTIES: To undertake research on causes of infertility in cattle in tropical environments. Particular areas of research would include: improvement in heifer fertility, post-partum anoestrus and selection indices correlated with fertility as an aid in breeding. Some research would be in collaboration with other scientists in the Division at Rockhampton as well as in Armidale and Sydney.

QUALIFICATIONS: Ph.D. degree in an appropriate field or equivalent, with research experience in reproductive physiology.

TENURE: Either a fixed term or indefinite appointment may be negotiated—both carry Superannuation benefits.

2 REFERENCE NUMBER 245/676

FIELD: ANIMAL BREEDING

LOCATION: PROSPECT, N.S.W.

DUTIES: The appointee will join a team undertaking research on improving the efficiency of wool production by sheep. The duties will be to design investigations to clarify the extent to which variation in the biology of the skin and the fleece are genetically determined.

QUALIFICATIONS: Ph.D. degree in an appropriate branch of genetics, or equivalent, plus demonstrable research ability. Preference will be given to applicants with a knowledge of sheep breeding.

TENURE: Indefinite with Superannuation.

SALARY FOR BOTH POSITIONS: Research Scientist or Senior Research Scientist: \$A14,292—\$A20,822 p.a. Outstanding applicants may be offered appointment at a higher level.

Applications (in duplicate), stating **FULL** personal and professional details, the names and addresses of at least two professional referees, and quoting reference number 245/675 or 245/676, should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, LONDON WC2R 3EH, by 20th January 1978. Applications in U.S.A. and Canada should be sent to: The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W. WASHINGTON D.C. 20036 U.S.A. 915(A.)

ROYAL POSTGRADUATE MEDICAL SCHOOL has a vacancy for a RESEARCH FELLOW

to work on the Comparison of immunological mechanisms of local and metastatic tumour spread and the effects of immunotherapy, tenable as soon as possible until June 1980.
Salary on the appropriate scale starting at £4,403 p.a. plus £450 London Allowance inclusive.
Application forms from Personnel Officer, RPMS, 150 Du Cane Road, London W12 0HS ref. no. 3/272(N). 918(A)

UNIVERSITY COLLEGE DUBLIN

Applications are invited by the Governing Body of the College for the following full-time statutory post:

PROFESSORSHIP OF CROP HUSBANDRY

Prior to application, further information (including application procedure) should be obtained from Mr J. P. MacHale, Secretary and Bursar, University College, Belfield, Dublin 4.

The closing date for receipt of completed applications is **THURSDAY FEBRUARY 2, 1978.** 947(A)

UNIVERSITY OF NEW ENGLAND

Armidale, New South Wales

PROFESSOR OF ANIMAL SCIENCE

The University of New England is seeking to fill the vacancy created by the impending retirement of Professor N. T. M. Yeates as Professor of Livestock Production.

As Professor of Animal Science (the proposed name for the present Department of Livestock Production) and will be appointed its Head for an initial five year period. In that capacity he will also be responsible, in consultation with the departments involved, for co-ordinating all undergraduate animal science teaching in the Faculty of Rural Science.

At present undergraduate teaching activities of the Department of Animal Science involve three courses in Rural Science and five in Economic Studies, all involving applied aspects of animal production. Research and postgraduate programmes and facilities presently encompass the fields of meat science, wool science, applied reproduction, growth and development and animal climatology.

The appointee must have high standing in a field of animal science and will be expected to develop further the Faculty's association with Australian agricultural industries.

Informal enquiries should be directed to the Dean of the Faculty of Rural Science, in the University.

Conditions of Service include assistance with travel and removal expenses and assistance to buy or build a home.

Superannuation will be on the F.S.S.U. pattern but members of the N.S.W. Superannuation Scheme may continue in that scheme if they wish.

Study leave is available and credit may be given for existing entitlements.

Salary: \$A30,786 p.a.

Further particulars relating to this chair from the Association of Commonwealth Universities (Apts.), or Staff Officer, University of New England, as appropriate.

Applications should include full details of qualifications, experience, research interests and publications and the names and addresses of three referees.

Applicants in the United Kingdom, Europe and America should forward their applications to the Secretary General, Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF, and send a copy to the Staff Officer.

Other applicants should forward their applications to the Staff Officer, University of New England, Armidale, New South Wales, Australia, without delay.

Closing date for applications **February 24, 1978.** 922(A)

KENYATTA UNIVERSITY COLLEGE—KENYA

(A constituent college of the University of Nairobi)

Applications are invited for the following posts:
ASSOCIATE PROFESSOR—CHEMISTRY DEPARTMENT. Candidates must have a Ph.D. in Chemistry and considerable experience of University teaching at least at Senior Lecturer level. Also required is evidence of successful research experience including the supervision of post-graduate students. Applicants should also have had some involvement in the training of secondary school teachers. Preference will be given to those who are qualified in one of the areas of Physical Chemistry.

ASSOCIATE PROFESSOR—PHYSICS DEPARTMENT. Applicants should hold a Ph.D. in Physics and have substantial University lecturing experience. All research specialities will be considered. Appointees will be required to teach graduate and under-graduate students, to plan and direct research, and participate in all academic activities of the College.

Salary scale K£3,600 to K£4,128 p.a. (at present under review). (K£1=£1.36 sterling). The British Government may supplement salaries by £4,332 p.a. (sterling) for married appointees and £3,042 p.a. (sterling) for single appointees (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Terms of service include subsidised housing, membership of S.S.S.F. or F.S.S.U. and a non-contributory medical scheme plus family passages. Detailed application (2 copies) including curriculum vitae and naming 3 referees should be sent airmail no later than January 30, 1978 to Registrar, Kenyatta University College, P.O. Box 43844, Nairobi, Kenya. Applicants resident in U.K. should also send one copy to the Inter-University Council, 90/91 Tottenham Court Road, London W1 0DT. Further details are available from either address. 861(A)

Opportunities in Virology

The Wellcome Foundation Ltd. is a major British-owned international pharmaceutical organisation which formulates, develops, manufactures and markets a wide range of human and veterinary medicines and vaccines.

At our Research Laboratories in Beckenham, Kent, we currently have opportunities for

Virologist—Vaccine Development

We seek a graduate microbiologist to carry out development work in the Department of Virology Research & Development.

The task will be to develop laboratory scale experiments into processes suitable for large scale production, and will involve the technologies of cell culture, virus growth and purification, stabilisation and freeze-drying of vaccines, etc. There will be close liaison with Research and Production scientists. The initial task will be collaboration in the

development of novel poliovirus vaccines. This post offers excellent career prospects to the right applicant. Candidates, probably aged 23-35, should have a good academic degree, although a PhD is not essential. The successful candidate will have a sound grounding in basic Virology, an interest in techniques, the ability to work closely with others and a practical frame of mind. Several years of laboratory experience in Virology would be a great advantage. On-the-job training will be provided.

Research Scientist—Veterinary Viruses

We seek a research scientist, with several years of post-doctoral experience in some relevant area of Virology, to work in the Department of Virology Research and Development on viruses causing disease in animals. Topics of current interest include herpes virus infections of small

and large animals and respiratory virus infections of bovines.

The successful candidate will have demonstrated an aptitude for a career in research. A veterinary qualification would be an added advantage.

Senior Technician—Virology Quality Control

to take technical charge of the Cytology Section of the Department of Viral Products Quality Control. Currently the Section comprises a member of the Scientific Staff and eight technicians. The work of the Section includes quality control of cell culture media and sera; quality control of viral vaccine substrates, the supply of a wide range of mammalian cell cultures; cytogenetic mutagenicity testing and cell culture research and development.

In addition to planning and supervising the work of the technical staff, the person appointed will be responsible for the maintenance of laboratory records, laboratory safety, training and general laboratory administration.

The successful candidate, qualified to BSc or at least HNC level, should have a minimum of 1-2 years' experience in cell culture techniques and karyology. Experience in laboratory administration would be an advantage.

The Laboratories are situated in pleasant parkland surroundings, within easy reach of Bromley and Beckenham, about 12 miles from Charing Cross. Conditions of employment are attractive and include four weeks' holiday, company pension fund, sick pay scheme, subsidised canteen and generous assistance with relocation expenses where appropriate.

Please write, indicating the post in which you are interested and giving details of relevant experience and qualification, to R. V. Sutton, Personnel Officer, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS.

955(A)

DIABETES RESEARCH

Biochemistry graduate with good degree required to join research group working on isotopically determined amino acid turnover (previous experience with amino acid analyses advantageous). Suitable as Ph.D. project. Application with full curriculum vitae to: Dr P. H. Sönksen, St Thomas's Hospital Medical School, London SE1 7EH. 931(A)

CAMBRIDGE UNIVERSITY APPLICABLE MATHEMATICS

The University expects to fill a **Lectureship or Assistant Lectureship in Applicable Mathematics** (e.g. in the mathematics of subjects such as probability, statistics, operational research, control and systems, or non-physical applications). Applications are invited. Further information from the Director of the Statistical Laboratory, 16 Mill Lane, Cambridge CB2 1SB. Telephone 65621, ext. 252.

Closing date: February 18, 1978. 887(A)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PATHOLOGY A TECHNICIAN

is required for a 3 year research project into immunological methods of diagnosis. Considerable laboratory experience essential preferably in bacteriology and biochemistry with H.N.C. or equivalent. Salary in region of £2,700 p.a. Applications in writing to The Superintendent, Department of Pathology, Tennis Court Road, Cambridge CB2 1QP. 874(A)

Product and Process Development

...with the accent on results

Over £7,700

The technology of our range of prepared pet-foods has to take account of a demanding and competitive market in which high quality and nutritional standards need to be maintained against a background of controlled manufacturing costs. Our Development Chemists are the vital focus of a continuing joint effort between marketing, commercial and production management to create products which will satisfy consumer demand and develop processes which will improve company performance.

These two related priorities require co-ordination skills of a high order, as well as the ability to direct projects right through from concept to manufacturing stage. The brief includes the evaluation of existing production processes, in addition to the origination of new ones; and the same applies to product development, where constant improvement of existing dry- and intermediate-moisture foods is as important as the

introduction of new products. In all cases, a sound commercial approach will be the key to effective results.

To be considered for this position you should ideally have proved yourself in a comparable commercial environment. Aged 25-35 with a degree in a relevant scientific discipline (preferably chemistry, biochemistry or food technology), you should have at least 3 years' experience in an R & D function - possibly obtained in process and/or product development within the food industry. This position, based at our modern Peterborough factory where we are putting particular emphasis on the development of dry- and intermediate- moisture foods, could lead to career development opportunities both within the R & D function and beyond. The competitive benefits package includes non-contributory pension and life assurance schemes and practical assistance with relocation.

**Pedigree
Petfoods**

A DIVISION OF MARS LIMITED

Please write briefly or ring for more written information and an application form to: Bob Phillips, Pedigree Petfoods, Melton Mowbray, Leicestershire LE13 1BB. Tel: Melton Mowbray 4141.

951(A)

THE UNIVERSITY OF MANITOBA FACULTY OF AGRICULTURE

Applications are invited for the position of
**PROFESSOR AND HEAD OF THE
DEPARTMENT OF PLANT SCIENCE**

Preference will be given to applicants with teaching experience, holding a Ph.D. degree or equivalent. Proficiency in oral and written communication is essential. A demonstrated competence in a field of plant research related to Canadian agriculture will be an important consideration.

The appointee will be responsible for the administration and co-ordination of teaching and research within the Department, and for liaison with the farm community, government, and industrial agencies.

The Department consists of 21 academic staff members who are active in teaching and research in the areas of agronomy, crop protection, cytogenetics and plant breeding, horticulture, and physiology-biochemistry.

EFFECTIVE DATE OF APPOINTMENT July 1, 1978.

CLOSING DATE FOR APPLICATIONS February 15, 1978.

Salary will be commensurate with experience and qualifications.

Applications, including curriculum vitae, and the names of three referees, should be addressed to:

Dean L. H. Shebeski
Faculty of Agriculture
The University of Manitoba
Winnipeg, Manitoba
R3T 2N2

893(A)

UNIVERSITY OF SYDNEY CHAIR OF PHYSICS (Theoretical Physics)

Applications are invited for the Chair of Physics (Theoretical Physics) which has become vacant on the resignation of Professor S. T. Butler, F.R.S. The School of Physics is concerned with the fields of optical astronomy, radio astronomy, plasma physics, theoretical physics, cosmic ray physics and solid state physics applied to solar energy. Applicants should have qualifications and interests in the general field of theoretical physics and particularly in the fields of plasma physics or astrophysics.

Salary \$A30,786 p.a.

A statement of Conditions of Appointment and Information for Candidates may be obtained from the Registrar, University of Sydney, NSW 2006, Australia, with whom applications close on March 10, 1978. Information also available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 938(A)

UNIVERSITY OF WISCONSIN Assistant Professor in Biochemistry

The Department of Biochemistry invites applications for the above position. Preference will be given to candidates in the areas of immunobiochemistry, plant biochemistry and X-ray crystallography. Female and minority candidates are especially encouraged to apply. Send detailed curriculum vitae, names of three references and a short statement of research interests to: H. F. DeLuca, Department of Biochemistry, University of Wisconsin, Madison, WI 53706. The University of Wisconsin is an equal opportunity/affirmative action employer. 827(A)

Aslib Director General

- THE Council of Aslib is to appoint a successor to Mr. Leslie Wilson who retires in 1978.
- As chief executive officer the Director General is accountable to the Council for the conduct and development of all aspects of the Association's business, which is to promote the effective communication, management and use of information in industry and commerce, central and local government, education and the professions.
- FORMULATION and interpretation of policy, and relations with member organisations, with industry, commerce, government and the academic world in the UK and overseas are the prime responsibilities.
- THE appointment demands the personal stature that stems from a record of creative achievement over a wide range of managerial responsibility requiring, especially, business acumen and communication skills.
- SALARY is negotiable well into five figures.

Write in complete confidence
to Sir Harold Atcherley as adviser to the Association.

TYZACK & PARTNERS LTD

10 HALLAM STREET and LONDON WIN 6DJ
12 CHARLOTTE SQUARE • EDINBURGH EH2 4DN

869(A)

UNIVERSITY OF OTAGO Dunedin, New Zealand CHAIR OF BOTANY

The University Council invites applications for the Chair of Botany at present occupied by Professor G. T. S. Baylis who is retiring at the end of 1978. Biological sciences are strongly represented in the University, and some preference may be shown towards candidates whose interests would encourage inter-disciplinary co-operation in teaching and research.

Professorial salaries, which are regularly reviewed, are fixed at various points within the range of NZ\$20,804 per annum to \$26,481 per annum, inclusive of cost-of-living allowances.

Further particulars are available from the Secretary General, Association of Commonwealth Universities (Appts), 36, Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on **February 28, 1978.**
921(A)

UNIVERSITY OF BRISTOL Department of Pharmacology POSTDOCTORAL RESEARCH ASSISTANT Re-advertisement

Applications are invited for a post funded by the Medical Research Council to work on the effects of halothane on neuronal microtubules in collaboration with Dr A. Livingston. Experience in electron microscopy, column chromatography and polyacrylamide gel electrophoresis an advantage.

The appointment will be for two years from March 1978 and the commencing salary will be up to £3,547 per annum and is superannuable.

Applications with the names of three referees should be sent by January 14, 1978 to Dr A. Livingston, Department of Pharmacology, The Medical School, University Walk, Bristol BS8 1TD. 824(A)

INTERIM DEAN FOR VETERINARY PROGRAMS

Tufts University seeks an experienced academic leader for the planning and development of a proposed School of Veterinary Medicine. The School is conceived as an integral part of an academic health center and as a medical, agricultural, and scientific resource for New England. It will join the Tufts University Schools of Medicine and Dental Medicine, the New England Medical Center Hospital, and a major nutrition research center at the Tufts Boston campus, and will share and strengthen existing basic science departments. The School will have its own clinical campus and will also provide clinical education at a number of eminent associated institutions throughout New England. Specialties are expected to develop in comparative medicine, laboratory animal medicine, nutrition, public health, toxicology, pathology, and aquatic animal and equine medicine. Candidates for the Interim Deanship should be veterinarians who have extensive and successful experience in the planning, administration, and support of veterinary institutions or health sciences programs. Distinguished research accomplishments and teaching and clinical experience are also important. Position available immediately. Send nominations and applications to: President Jean Mayer, TUFTS UNIVERSITY, Medford, MA 02155. An Equal Opportunity/Affirmative Action Employer. 940(A)

TECHNICIAN— Electrophysiological Experience

Position available immediately for someone with micro-electrode experience to work with tissue cultured neurons. Electronics and computer experience highly desirable. Tissue culture experience desirable but not essential. Salary to \$10,000 with annual raises. Contact Dr Frederick Sachs, Dept. of Pharmacology, 127 Farber Hall, State University of NY at Buffalo, Buffalo, NY 14214 U.S.A. An Affirmative Action/Equal Opportunity Employer. 833(A)

M.R.C. CLINICAL RESEARCH CENTRE (Northwick Park Hospital) Watford Road, Harrow Middx. HA1 3UJ

The division of communicable diseases is seeking a biochemist with at least 5 years postgraduate virological experience or a virologist of similar experience with biochemical expertise to work on the identification and analysis of the antigens of coronaviruses and the development of methods for detecting them and the corresponding antibodies. Candidates must be over 27 years of age and have a minimum of three years postdoctoral experience.

Salary from £4,607 p.a. to £5,219 plus £450 London allowance. Further details and application form obtainable from Mrs. J. Tucker-Bull. Closing date January 14. Please quote reference 108/1/4/4053. 913(A)

LOTHIAN HEALTH BOARD BASIC GRADE CYTOGENETICIST

There is a vacancy for either a full time graduate or two part time graduates in the Area diagnostic cytogenetics service based at the Pathology Dept. Royal Hospital for Sick Children, Edinburgh. Experience in human cytogenetics desirable. Further particulars of the post can be obtained from Dr A. D. Bain, Pathology Department, Royal Hospital for Sick Children, Edinburgh. Tel: 031-667 1991, Ext. 270.

Salary scale £2,277 per annum to £3,933 per annum plus salary supplement of £312 per annum plus phase II salary supplement with placement according to qualifications and experience.

Applications, which should be type-written, giving particulars of age, qualifications, and previous experience, together with the names and addresses of two referees should be lodged with the Secretary, 11 Drumsheugh Gardens, Edinburgh EH3 7QQ, by 19 January, 1978. 930(A)

Wellcome

Section Head

Chemical Development Laboratories

Natural Products Chemistry

The Wellcome Foundation Limited, a leading British-owned international pharmaceutical organisation, formulates, develops and manufactures a wide range of chemical and pharmaceutical products. Annual turnover is in excess of £290 million with profits being donated to further medical and veterinary research.

We currently have an opportunity for a Section Head, Natural Products Chemistry, within the Process Development Group of the Chemical Development Laboratories at Dartford, Kent.

The post will involve working in close liaison with both research and production teams involved in the development of production scale procedures from research prototypes and the evaluation of new and existing processes, as well as providing a service for the resolution of production difficulties.

Candidates should be organic chemists with a good honours degree or a Ph.D. in Chemistry and several years experience of the specialised methods and techniques required for the purification and isolation of naturally occurring substances (both chemical and proteinaceous) of pharmaceutical interest.

We offer an attractive salary, dependent upon qualifications and experience. Excellent conditions include 4 weeks' annual holiday and generous assistance with relocation expenses where appropriate.

For an application form, please write to or ring
Ian Griffiths, Personnel Division, The Wellcome
Foundation Limited, Temple Hill, Dartford, Kent
Telephone: Dartford 23488, ext. 2061

876(A)

FACULTY OPENING IN BIOCHEMISTRY University of Illinois Champaign-Urbana

The Department of Biochemistry is seeking applicants for a tenure track appointment at the level of Assistant Professor or higher to begin August, 1978. Applicants should be qualified to teach biochemistry courses at undergraduate or graduate levels. Only candidates who have demonstrated excellence in research and who are prepared to establish an active research program will be considered; preference will be given to those who have received graduate and postdoctoral training in strong research environments. The minimum salary at the Assistant Professor level is \$15,000 for a nine-month appointment; salaries at higher ranks are negotiable. For full consideration, application materials, including a curriculum vitae, a list of publications, a brief description of research interests and three letters of reference should be sent by February 1, 1978 to:

Professor Lowell P. Hager, Head
Department of Biochemistry
University of Illinois
Urbana, Illinois 61801
Telephone: (277) 333-3945.

The University of Illinois is an Affirmative Action/Equal Opportunity Employer. 836(A)

DEPARTMENT OF NUTRITION AND FOOD SCIENCE MASSACHUSETTS INSTITUTE OF TECHNOLOGY FACULTY POSITION

The Department, a large multidisciplinary teaching and research unit with activities in all principal areas of nutrition and food science is seeking an applicant to fill the following faculty position:

An M.D., with research training and preferably with a Ph.D. degree, and experience and a major interest in human and clinical nutrition. The appointee will be expected to teach graduate level courses concerned with human and clinical nutrition, to develop a vigorous research programme and become actively involved in the research programmes of the M.I.T. Clinical Research Center.

The appointment will be at the Assistant or Associate Professor rank, depending upon the qualification of the successful applicant.

Curriculum vitae, together with representative publications and the names of five referees should be submitted before February 1, 1978 to: Dr V. R. Young, Chairman Search Committee, Room 56-331, Massachusetts Institute of Technology, Cambridge, MA 02139, USA.

M.I.T. is an Equal Opportunity Employer. Representatives of minority groups are urged to apply. 830(A)

THE OPEN UNIVERSITY

Faculty of Science

RESEARCH ASSISTANT IN BIOPHYSICS

The Research Assistant will work at the Open University Research Unit at Boars Hill, Oxford, on a research project supervised by Professor G. F. Elliott and concerned with biological polyelectrolytes, notably muscle and cornea. Candidates should hold at least a good first degree in Physics, Chemistry or Physiology. The Assistantship is available from January 1978 (or as soon as possible thereafter) to December 1980. Commencing salary will be within the Research Assistant 1B scale £2,904 to £3,333 (age 26) to £4,190 p.a.

Details and application forms are available, by postcard request please, from The Personnel Manager (RAB3), The Open University, P.O. Box 75, Walton Hall, Milton Keynes MK7 6AL, or by telephone from Milton Keynes 63868. Closing date for applications: January 19, 1978.

878(A)

KENYATTA UNIVERSITY COLLEGE—KENYA

Applications are invited for the following posts in the DEPARTMENT OF MATHEMATICS:

SENIOR LECTURER. Applicants should be holders of a Ph.D. or equivalent and must have substantial experience in teaching and research at University level. Ability and interest to plant and execute new course programmes for both undergraduates and postgraduates are essential qualifications. Experience in teaching in a teacher-education institution will be an added advantage.

LECTURER. Applicants should have a good postgraduate degree, preferably a doctorate, in pure or applied mathematics and/or statistics. They should have teaching and research experience at University level.

Salary scales (under review): Senior Lecturer £K2,772 to £K3,600 p.a. Lecturer £K1,800 to £K3,096 p.a. (£K=£1.34 sterling). The British Government may supplement in range £3,354 to £4,128 p.a. (sterling) for married appointees and £2,184 to £2,880 p.a. (sterling) for single appointees (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Terms of service include subsidised housing, membership of S.S.S.F. or F.S.S.U. and a non-contributory medical scheme and family passages. Detailed applications (2 copies) including curriculum vitae and naming 3 referees to be sent airmail to Registrar, Kenyatta University College, P.O. Box 43844, Nairobi, Kenya by January 25, 1978. Applicants resident in U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars are available from either address. 860(A)

THAMES POLYTECHNIC SCHOOL OF MATERIALS SCIENCE AND PHYSICS X-RAY AND NUCLEAR LABORATORY TECHNICIAN (Grade 5)

Applications are invited for a technician for the X-ray and nuclear laboratories who will be required to operate X-ray equipment, handle radioactive sources and be responsible for keeping exposure records. Candidates should have a recognised apprenticeship or H.N.D./H.N.C. qualification and at least eight years' relevant experience.

Salary scale: £3,027 to £3,483 including London weighting plus personal allowance (i.e. 5% of gross pay; min. £2.50, max. £4.00).

Further particulars and form of application may be obtained from the Staffing Officer, Thames Polytechnic, Wellington Street, London SE18 6PF, to whom completed applications should be returned as soon as possible. 903(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the following posts in the

DEPARTMENT OF AGRICULTURAL ECONOMICS

1. ASSOCIATE PROFESSOR IN PRODUCTION ECONOMICS AND FARM MANAGEMENT

Applicants must possess a good honours degree in Agricultural Economics, Economics or Agriculture and a Ph.D. in Agricultural Economics. Sound knowledge of planning techniques and decision theory is essential, supported by research experience and reviewed publications. Academic duties will mainly concern lecturing and research supervision of M.Sc. and Ph.D. students in the fields specified. Occasional support lecturing in general economics and research methods subjects will be expected. Administration responsibilities will involve those associated with a senior appointment in an active and growing Department.

2. SENIOR LECTURER

Applicants, who should possess a Ph.D. must have relevant teaching and research experience in Agricultural Economics at University level. The appointee should have a good background in Economic Theory and Quantitative Techniques and should be capable to apply these in the field of agriculture. The appointee will be expected to teach at both undergraduate and graduate levels. Experience in supervision of research is essential.

Salary Scales: Associate Professor K£3,600 to K£4,128 p.a. Senior Lecturer K£2,772 to K£3,600 p.a. (K£1=£1.35 sterling). Salaries are currently under review. The British Government may supplement salary in range £4,128 to £4,332 p.a. (sterling) for married appointee or £2,880 to £3,042 p.a. (sterling) for single appointee (normally free of all tax and reviewed annually) and provide children's education allowances and holiday visit passages. F.S.S.U.; family passages; various allowances. Detailed applications (2 copies) including curriculum vitae and naming 3 referees should be sent air mail to Registrar, (Recruitment and Training), University of Nairobi, P.O. Box 30197, Nairobi, Kenya. Closing date January 27, 1978. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 894(A)

UNIVERSITY OF SUSSEX BIOCHEMISTRY LABORATORY POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a position sponsored by the Wellcome Trust to join a group studying the control of proliferation in mitogen-stimulated lymphocytes. Candidates should have a background in biochemistry or cell biology.

Salary will be on the Research Fellow 1A scale, £3,333-£5,627 p.a., and the post is available until September 30, 1979. Applications, with curriculum vitae and the names of two referees, should be sent to Dr John Kay, School of Biological Sciences, University of Sussex, Falmer, Brighton BN1 9QG. 944(A)

MEDICAL RESEARCH COUNCIL NATIONAL INSTITUTE FOR MEDICAL RESEARCH

W.H.O. Special Programme for Research and Training in Tropical Diseases

A vacancy exists for a cell biologist or biochemist to join a group working on the control of variable antigen synthesis in malaria parasites. The appointment will be for up to three years and will be in the present salary range £3,995 to £5,219 p.a. according to age and qualifications plus £450 p.a. London Allowance; superannuation provision. Recent Ph.D. graduates or students expecting to complete their doctorate in 1978 are invited to apply before February 12, 1978.

Applications, giving details of qualifications, experience and the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA. 886(A)

Electron Microscopist

Applications are invited from experienced microscopists (preferably graduates in a Biological Science) to take full responsibility for a comprehensive Services Section within the Research Division of Beecham Pharmaceuticals.

The section provides a service to the Division encompassing all aspects of the R & D programmes, including many microbiological and biomedical problems. This post will present an opportunity to expand the application of a wide range of techniques in a multi-disciplinary industrial research environment.

The section is well equipped with a Philips EM 300 TEM, a new Philips SEM 501 and Zeiss microscope facilities. There is provision for histology, ultramicrotomy, freeze etch/vacuum coating and other routine preparatory systems besides comprehensive dark room equipment, within a purpose-built suite.

Ideally, applicants, male or female, should have experience in electron microscopy applied to histopathology and/or microbiology, with a broad technical knowledge of light microscopy, transmission and scanning E.M. and associated techniques. A practical and innovative approach is essential.

Brockham Park is situated near Dorking, free transport being available to and from local stations. Assistance can be given in finding accommodation in the area. The Company will offer a good starting salary and benefits which include a non-contributory pension scheme, free life assurance, flexible working hours, excellent sports and social facilities, etc.

Please apply, summarising professional qualifications and experience to:

Miss E A Gunn, Site Personnel Officer, Beecham Pharmaceuticals Research Division, Brockham Park, Betchworth, Surrey RH3 7AJ

Beecham

Pharmaceuticals

UNIVERSITY OF DUBLIN

Trinity College

CHAIR OF CHEMISTRY

and

HEADSHIP OF DEPARTMENT

Applications are invited for appointment to these posts which will fall vacant on October 1, 1978, following the retirement of the present holder Dr Wesley Cocker. While the University is not committed to an appointment solely in one field of Chemistry, applications from persons with a special interest in Inorganic Chemistry will be particularly welcome.

Further particulars, both of the present activities of the department of Chemistry, and of the conditions of appointment to the Chair and to the Headship, may be obtained from:

Mr G. H. H. Giltrap, Secretary to the College,
Trinity College, Dublin 2

to whom formal application should be made, preferably not later than January 23, 1978.

571(A)

FORENSIC SCIENCE

Opportunities for Chemists/Biochemists

Opportunities in Forensic Science

Forensic investigation makes wide-ranging demands on the abilities of chemists and biochemists. Serology, enzymology and immunology techniques are employed in comparing blood, saliva and semen stains. Identification of plant and animal materials and textile fibres demands a variety of chemical and taxonomic approaches, and skilled use of the microscope. The modern chemical and physical methods of analysis are involved in the investigation of paint, glass and trace materials, whilst toxicology and drug identification require some specialised knowledge of organic analysis.

WHERE YOU COULD WORK

Vacancies exist at Cardiff and Bristol (both moving to Chepstow in 2-3 years), and at Aldermaston, Birmingham, Chorley and Wetherby.

The successful candidates will initially help experienced colleagues. Later, they will take responsibility for their own investigations and reports, and act as expert witnesses. Their work may at first overlap several of the areas mentioned above, but they will have opportunities to specialise.

Candidates, normally aged under 27, must have a degree, or equivalent qualification, in Biochemistry or Chemistry. Those with experience in any of the above fields are particularly invited to apply. *Final year students will not be considered.*

Appointment will be as Scientific Officer, with starting salary within the range of £2590-£4030. There are promotion prospects and a non-contributory pension scheme.

For further details and an application form (to be returned by 20 January 1978) write to Civil Service Commission, Alencon Link, Basingstoke, Hants. RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote Ref. SB/17/LA.*

HOME OFFICE 939(A)

GLASGOW INSTITUTE OF RADIOTHERAPEUTICS AND ONCOLOGY

Applications are invited for the position of
SENIOR SCIENTIFIC OFFICER

The successful candidate will lead a small team who will be investigating the biological effectiveness of various radiotherapy regimes. This is a postdoctoral appointment supported by an M.R.C. Project Grant. Candidates need not necessarily be radiobiologists but they should have worked with small animals and some knowledge of biophysics would also be useful. The appointment is for three years from April 1, 1978. The salary is that for the Senior Scientist grade in the National Health Service in the range £4,957 to £5,362.

Applications with curriculum vitae, two referees and a day-time telephone number should be sent before January 27 to:-

Dr A. H. W. Nias,
Radiotherapy Department,
Belvidere Hospital,
Glasgow G31 4PG.
(Tel. 041-554 1855)

946(A)

ASSISTANT/ASSOCIATE PROFESSOR DEPARTMENT OF BIostatISTICS

Ph.D. in Statistics, Applied Mathematics or equivalent background, plus teaching and consulting experience in applications of statistics or mathematical methods to problems in biology, medicine, or public health. Applications including CV and three letters of recommendation to Dr Frederick Mosteller, Department of Biostatistics, Harvard School of Public Health, 677 Huntington Avenue, Room 706, Boston, MA 02115. Harvard University is an Equal Opportunity/Affirmative Action Employer. 912(A)

GUY'S HOSPITAL MEDICAL AND DENTAL SCHOOLS RESEARCH ASSISTANT (Immunologist/Biochemist)

Pre- or postdoctoral immunologist or biochemist having experience in immunochemical techniques required for a period of two years in the first instance. The person is required to investigate immune responses to Streptococcus mutans in rhesus monkeys.

Salary according to qualifications and experience, with £450 per annum London Allowance and superannuation.

Apply in writing, with curriculum vitae, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. I.M.4. 924(A)

DEPARTMENT OF PHYSICS ASSISTANT PROFESSORSHIP

Subject to adequate funding, a position may become available July 1, 1978 in one of the following fields:

QUANTUM OPTICS BIOPHYSICS

Salary depends on qualifications. The closing date for applications is March 31, 1978.

Exceptional candidates in other fields may be considered.

All correspondence should be addressed to:

Professor Luis de Sobrino, Chairman,
Appointments Committee,
Department of Physics,
The University of British Columbia,
2075 Wesbrook Place,
Vancouver, British Columbia,
Canada V6T 1W5. 823(A)

THE UNIVERSITY OF LEEDS RESEARCH FOR SCHOOL SCIENCE MASTERS

Applications are invited from graduate Science Masters in Schools to take part in research in the Procter Department of Food Science for a period of four weeks in the summer vacation. Two places are available in 1978 and grants to cover expenses incurred are available from the Worshipful Company of Skinners through its Lawrence Atwell's Charity. The research will be of a chemical or physical nature and topics will be selected with subsequent continuation in school laboratories in mind either as part of the school science syllabus or as a research project.

Applications, giving details of career and interests, and the names of two referees, should be sent as soon as possible to the Head of Department, Procter Department of Food Science, University of Leeds LS2 9JT. 948(A)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (University of London)

Denmark Hill, London SE5 8RX
DEPARTMENT OF

OBSTETRICS & GYNAECOLOGY

Applications are invited from graduates or qualified people for the post of Research Technician on a project mainly involving tissue culture and cytogenetics as well as histological and histochemical techniques in the area of prenatal diagnosis of inherited diseases.

Starting salary £3,112 inclusive.

For informal enquiries please contact Dr J. Singer on 01-274 6222, extension 2349. Applications in writing giving full details of qualifications and experience should be sent to the Secretary of the Medical School at the above address by January 19, 1978. 917(A)

THE UNIVERSITY OF JUBA—SUDAN

Applications are invited for the following posts in the

COLLEGE OF NATURAL RESOURCES AND ENVIRONMENTAL STUDIES

1. PROFESSOR / READER / SENIOR LECTURER / LECTURER IN ANIMAL PRODUCTION.
2. PROFESSOR / READER / SENIOR LECTURER / LECTURER IN FISHERIES.
3. PROFESSOR / READER / SENIOR LECTURER / LECTURER IN WILDLIFE.
4. PROFESSOR / READER / SENIOR LECTURER / LECTURER IN FORESTRY.
5. PROFESSOR / READER / SENIOR LECTURER / LECTURER IN CROP PRODUCTION.
6. PROFESSOR / READER / SENIOR LECTURER / LECTURER IN SOIL CHEMISTRY.
7. PROFESSOR / READER / SENIOR LECTURER / LECTURER IN GENERAL BIOLOGY (Botanist).
8. PROFESSOR / READER / SENIOR LECTURER / LECTURER IN MATHEMATICS.
9. PROFESSOR / READER / SENIOR LECTURER / LECTURER IN PHYSICS.

Salary scales: Professor £54,135 p.a. Reader £53,625 p.a. Senior Lecturer £52,465 to £53,000 p.a. Lecturer £51,600 to £52,400 p.a. (£51=£50.63). The British Government may supplement salaries in range £2,982 to £3,558 p.a. (sterling) for married appointees or £1,410 to £1,980 p.a. (sterling) for single appointees (normally free of all tax and reviewed annually) and provide children's education allowances and holiday visit passages. Family passages; various allowances; superannuation scheme; annual overseas leave. Salary scales and rates of supplementation are under review. Detailed applications (2 copies), including a curriculum vitae and naming referees, should be sent by air mail, not later than January 20, 1978 to the Secretary General, University of Juba, P.O. Box 82, Juba, Sudan. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. 858(A)

THE QUEEN'S UNIVERSITY
OF BELFAST

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL
RESEARCH FELLOW/
RESEARCH ASSISTANTS

Applications are invited for three positions for work with Dr J. J. Rooney and Professor K. J. Ivin on the mechanism of olefin metathesis, especially in relation to the ring-opening polymerization of cycloalkenes:

1. Research Fellow: £3,333 to £4,403 (under review) with F.S.S.U./U.S.S.
2. Research Assistant: £2,904 to £4,190 (under review) with F.S.S.U./U.S.S.

One research assistant post will be tenable for two years. The other posts will be tenable for one year initially and may be renewed annually for further periods. Commencing salary will be at point appropriate to age, qualifications and experience.

Applications, giving a curriculum vitae and the names and addresses of two referees, should be sent to The Personnel Officer, The Queen's University of Belfast BT7 1NN as soon as possible. 866(A)

LINCOLN COLLEGE

New Zealand

RESEARCH ECONOMIST
(RUMINANT PRODUCTION SYSTEMS)
AGRICULTURAL ECONOMICS
RESEARCH UNIT

Applications are invited for the above mentioned position from persons with higher degree qualifications in Agricultural Economics/Management or Agricultural Science. Applicants should have some experience in the application of quantitative techniques to both production and management problems.

Commencing salary according to qualifications and experience within the range of NZ\$7,386 to \$12,543 per annum. At present salaries are supplemented by an "Interim Special Allowance" of 3.5%.

Travel and removal expenses reimbursed up to specified limits. Government Superannuation available.

Conditions of Appointment are obtainable from the Association of Commonwealth Universities (Apts), 36, Gordon Square, London WC1H 0PF, or from the Registrar of the College.

Applications close on February 17, 1978. 923(A)

NATIONAL COUNCIL
FOR SCIENTIFIC RESEARCH

Applications are invited from suitably qualified persons for the post of:

MATERIALS ENGINEER/
SCIENTIST

Applicants for the post must have a degree in Materials Engineering/Science with a minimum of 5 years experience in research and development work.

The successful candidate will be required to initiate and carry out research and development work on the utilisation of local raw materials in the production of soft boards or development of alternative roofing materials for low cost housing, and to provide technical advice on the production and usage of building materials.

Salary will be according to qualifications and experience on the following scales:

Senior Principal Professional Officer: K7,812 x 204 - K8,016 x 216 - K8,232

Principal Professional Officer: K6,756 x 216 - K6,972 x 288 - K7,200 x 204 - K7,608

Senior Professional Officer: K5,424 x 288 - K5,712 x 300 - K6,012 x 312 - K6,324

Applications giving full personal details, qualifications, experience and names and addresses of three referees should be submitted to:

The Secretary General,
National Council for Scientific Research,
PO Box CH 158,
LUSAKA,
ZAMBIA.

Wellcome

Immunologist

Department of Experimental Immunobiology

The Wellcome Foundation Limited is a major British-owned international pharmaceutical organisation. Our Research Laboratories at Beckenham are looking for a post-doctoral scientist to work on a programme concerned with the effect of pharmacological agents on experimental autoimmune disease. Particular emphasis will be directed towards an analysis of the involvement of suppressor cells. The appointment will be available from 1 April 1978, for a period of 2-3 years in the first instance.

Applicants should be able to provide evidence of an innovative approach to immunobiological research.

The starting salary will depend upon experience but is not expected to be less than £4,500 p.a. Excellent working conditions and benefits include generous relocation expenses, where appropriate.

Please apply, giving details of qualifications and previous research experience, to the Personnel Manager, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS

877(A)

Chemical Defence Establishment, Porton Down, Wilts.

Biologist/Chemist

... to supervise the work of the Tissue Culture Unit in the Medical Division of the Department of Toxicology and Pathology.

The successful candidate will implement and develop suitable tests to use in the assessment of short and long term toxicity in vitro. Cell and tissue culture methods will be applied to a study of the toxicological and biological activity of a wide range of chemicals. The use of rapid screening techniques to complement current toxicological studies will be important. The work involves development and use of in vitro tests for mutagenicity and carcinogenicity.

Applicants, normally aged under 32, must have a good honours degree, or equivalent, in Biology or Chemistry and have post graduate experience in mammalian tissue cell culture techniques. A working knowledge of histology, histochemistry, photomicrography, cinemicrography and autoradiography would be desirable.

Appointment will be as Senior Scientific Officer (£4,700-£6,300) or Higher Scientific Officer (£3,740-£4,975) according to age, qualifications and experience. Starting salary may be above the minimum at each level.

For application form (to be returned by 27 January 1978) write to:
Mr F. C. G. Philbrick, Chemical Defence
Establishment, Porton Down, Wiltshire
Please quote ref: SA/3/FM

881(A)

DIRECTOR

Division of Cancer Cause and Prevention National Cancer Institute

The National Cancer Institute is recruiting for a scientist who will direct, coordinate, and conduct:

- *A nationwide program of laboratory, field, biometric, and epidemiologic research on the cause and natural history of cancer and the means for preventing cancer through an intramural and collaborative program.
- *A program that serves as the focal point for the Federal Government on the synthesis of clinical, epidemiological, and experimental data relating to cancer cause and prevention.
- *A program that evaluates mechanisms of cancer induction by viruses, environmental carcinogenic hazards and the natural history of neoplasms.
- *The research work of a professional and support staff of 590 employees.

Candidates for this position should have an advanced professional degree (Ph.D., M.D., or equivalent) in a medical, biological, physical or related health science, and at least three years of professional specialised experience in Biomedical Science Administration involving two or more Scientific Disciplines (e.g., chemistry, biology, microbiology, etc.). The candidate's professional experience must demonstrate the successful program planning, evaluation, and administration of high caliber biomedical research or clinical programs relating to human disease problems, and extensive experience as an independent investigator in clinical, basic, applied, developmental, or epidemiological research activities. Candidates will be evaluated on their scientific leadership and experience, scientific recognition, training and education, and honors and awards. The filling of this position is subject to the approval of the Civil Service Commission.

This is a career Civil Service position at the Supergrade level with liberal government benefits and salary ranging from \$42,423 to \$47,500. Appointment may also be made through the Commissioned Corps of the U.S. Public Health Service.

Submit Curriculum Vitae, Bibliography and Personal Qualifications Statement (SF-171) by 10 February, 1978, to: Mrs. Elizabeth W. Stroud, NCI Personnel Office, National Institutes of Health, Public Health Service, 9000 Rockville Pike, Building 31, Room 3A19, Bethesda, Md. 20014. An Equal Opportunity Employer M/F.

NATIONAL INSTITUTES OF HEALTH

843(A)

TECHNICIAN

required in Muscle Research Centre, Hammersmith Hospital, to work principally on electron microscopy of muscle. O.N.C./H.N.C. or equivalent and experience in E.M. techniques preferable. Post tenable until October 1978 in the first instance. Salary according to age and experience on the scale £2,982 to £3,808 p.a. plus London Weighting.

Applications with full curriculum vitae and names and addresses of two referees to Professor V. Dubowitz, Department of Paediatrics and Neonatal Medicine, Hammersmith Hospital, Du Cane Road, London W12 0HS. 899(A)

PRINCETON UNIVERSITY DEPARTMENT OF BIOCHEMICAL SCIENCES

Assistant Professor position: Biochemist or molecular or cell biologist with strong background in either physical biochemistry or protein chemistry. Applicants should send vitae, bibliography, list of referees and outline of research program to: Dr Jacques R. Fresco, Chairman, Department of Biochemical Sciences, Princeton University, Princeton, NJ, NS, 08540. An affirmative action/equal opportunity employer.

873(A)

IMPERIAL CANCER RESEARCH FUND Bursaries for Training in Research

A small number of Bursaries will be awarded at the laboratories in Lincoln's Inn Fields for full-time studies leading to higher Degrees in research fields relevant to cancer, that include chemistry, cell and molecular biology.

The awards will be tenable for three years from 1st October, 1978 with a non-superannuable grant of £2,640 a year (subject to tax) and, in some cases, additional allowances.

Applications are invited from British subjects, normally resident in the U.K. and not over 25 years of age, who hope to obtain First or Upper Second class Honours Degrees in Science in 1978.

Further details and application forms are available from:

The Personnel Officer
Imperial Cancer Research Fund
Lincoln's Inn Fields
London WC2A 3PX

Completed applications should reach the Director of Research at the above address not later than 14th February, 1978. 904(A)

UNIVERSITY OF READING LECTURESHIP IN PHYSIOLOGY & BIOCHEMISTRY

Applications are invited for the above post from graduates in Biochemistry, Physiology, Pharmacology or Veterinary Science, with active research interests in some area of pharmacology. The person appointed should take up duties as soon as possible.

Further information may be obtained from the Registrar (Room 214, Whiteknights House), The University, Whiteknights, Reading RG6 2AH, by whom applications should be received not later than February 1, 1978. 837(A)

UNIVERSITY OF SOUTHAMPTON DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH FELLOW, salary range £3,333—£3,547. One year appointment to start as soon as possible. The project concerns the study of absorption at metal electrodes by modulated specular reflectance spectroscopy. Experience in electrochemistry or the study of surfaces by optical methods will be a considerable advantage. A curriculum vitae and the names of two referees should be sent to Dr A. Bewick, Department of Chemistry, The University of Southampton, Southampton SO9 5NH. 936(A)

THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF BUILDING SCIENCE

Applications are invited from men and women for 2 POSTDOCTORAL RESEARCH POSTS, RANGE 1A, and 1 RESEARCH ASSISTANT RANGE 1B.

Post A: Range 1A up to £3,761 a year.

Tenable for three years. To work on the environmental performance of windows with special reference to energy conservation, solar energy and climatic design using interactive computing techniques. Postgraduate research experience in building environmental engineering, building climatology, physics or some other related discipline, plus some experience in computer programming in FORTRAN required.

Post B: Range 1B up to £3,761 a year.

Tenable for three years. To work on the assessment of dynamic wind loads on buildings using small scale aerodynamic models in wind tunnels. Postgraduate research experience in wind engineering research required. Knowledge of structural dynamics and/or mini computer analysis would be useful.

Post C: Range 1B up to £3,119 a year.

Tenable for 1 to 2 years. To work on geographical variations in the transmission of the atmosphere in the U.K. for solar radiation in relation to other climatological factors influencing heat transfer from buildings. Suitable graduate experience in Applied Climatology, Applied Meteorology or Environmental Science required. Experience in the use of digital computers would be an advantage.

Further particulars from the Registrar and Secretary, The University, Sheffield S10 2TN to whom applications should be sent by January 20, 1978. Quote Ref. R. 62/G. 949(A)

AUSTRALIAN WINE RESEARCH INSTITUTE Adelaide, South Australia RESEARCH MICROBIOLOGIST

Duties: To carry out a programme of microbiological and biochemical research in oenology; this would include yeasts and lactic acid bacteria with studies of related enzymatic processes in winemaking; to investigate and advise on problems of spoilage of wine, and to maintain the Institute's yeast culture collection.

Qualification and Experience: Ph.D. or equivalent research experience in relevant field. Some background in biochemistry and microbiology. Skill in sensory evaluation would be an advantage.

Salary: Research Scientist \$14,292 to \$17,548 p.a., plus immediate entry to a contributory superannuation scheme.

Applications, which will be treated in strictest confidence, should include full personal and professional details and the names of at least two referees and should be submitted to:-

The Chairman,
Council of the Australian
Wine Research Institute,
Post Office,

Glen Osmond, South Australia, 5064.
by January 31, 1978. 909(A)

THE UNIVERSITY OF THE WEST INDIES, TRINIDAD

Applications are invited for the vacant temporary post of SENIOR LECTURER/TURER/ASSISTANT LECTURER in the DEPARTMENT OF LIVESTOCK SCIENCE, FACULTY OF AGRICULTURE. Preference will be given to applicants holding a first degree in animal science or veterinary medicine with postgraduate qualifications in animal physiology. Interest and experience in the physiology of dairy cattle reproduction (infertility) and/or adaptation of ruminants to hot, humid climates would be an advantage. The appointment will be for 2 years with the possibility of extension for a total of 5 years. Salary Scales (1977-78): Senior Lecturer: TT\$25,827 to TT\$34,017 p.a. Lecturer: TT\$19,071 to TT\$29,799 p.a. Assistant Lecturer: TT\$15,480 to TT\$16,974 p.a. (£1 sterling = TT\$4.39). F.S.S.U. Unfurnished accommodation if available at 10% or furnished at 12½% or housing allowance of 20% of pensionable salary. Up to five full economy passages on appointment and on normal termination. Study and Travel Grant. Detailed application naming three (3) referees to Secretary, U.W.I., St Augustine, Trinidad. Details of post sent to all applicants. 859(A)

RHODES UNIVERSITY

Grahamstown, South Africa

**Applications are invited for the post of
SENIOR LECTURER/LECTURER
IN ZOOLOGY**

from July 1, 1978 or as soon as possible thereafter.

The salary scales are:-

SENIOR LECTURER: R8,460 by R360 to R9,900 by R450 to R11,250 per annum.**LECTURER:** R6,300 by R360 to R9,180 per annum.

(Note: £1 sterling=approximately R1.59)

The initial salary will be determined according to qualifications and experience. In addition a supplement of 10% on the above scales and a vacation savings bonus are payable. The successful applicant will become a member of the University's pension and medical aid schemes.

The successful applicant will be required to teach invertebrate biology. Research interests in either freshwater or estuarine biology will be a strong recommendation.

Further particulars and application forms may be obtained from the Registrar, Rhodes University, Grahamstown, 6140, South Africa to whom completed applications together with a recent photograph should be sent by March 15, 1978. 895(A)

**UNIVERSITY OF SURREY
DEPARTMENT OF BIOCHEMISTRY
RESEARCH OFFICER**

An interesting vacancy exists for a Research Officer to work on Tryptophan and its metabolites with particular reference to biological rhythms.

The vacancy is for two years and would suit a graduate (male or female, under 25 years of age) in a biological subject, preferably with some experience of fluorimetry and/or radio immunoassay and an interest in the biochemistry of the nervous system.

The salary is £2,904 p.a., but this is at present subject to review.

Applications in the form of a curriculum vitae, including the names and addresses of two referees, should be sent to the Assistant Secretary (Personnel), University of Surrey, Guildford, Surrey GU2 5XH, as soon as possible. 916(A)

**UNIVERSITY OF BRISTOL
DEPARTMENT OF PHYSICS
RESEARCH ASSISTANT**

Applications are invited for a Research Assistantship funded by N.E.R.C. for an investigation of the frost cracking of rocks. The study would involve laboratory and theoretical work to elucidate the basic physics involved when ice freezes in a crack in a solid, generating stresses which propagate the crack. Photoelastic techniques would be used; some research experience in crack problems is desirable. The appointment is for three years with a starting salary of £3,761 p.a. (under review).

Applications, with curriculum vitae, details of research experience and names and addresses of two referees, should be sent to Professor J. F. Nye, H. H. Willis Physics Laboratory, Tyndall Avenue, Bristol BS8 1TL by February 2, 1978. 871(A)

**THE UNIVERSITY OF LEEDS
THE UNIT FOR CANCER RESEARCH**

Applications are invited for the post of BIOCHEMIST to join a research team in the above Unit and the Department of Chemical Pathology. Candidates should have previous clinical laboratory experience. The team is studying biochemical discriminants in cancer treatment, the work will involve development of protein and enzyme analysis and their evaluation in cancer patients.

Salary on the IB Scale for Research and Analogous Staff: £2,904 to £4,190. Appointment will be for one year with the possibility of renewal for a further two years.

Apply to: Professor E. H. Cooper, Unit for Cancer Research, University of Leeds, Leeds LS2 9JT. 907(A)

Scientist for Research Product Management

In the Boots Company the activities involving the development of new medical and over the counter pharmaceutical products are co-ordinated and progressed by Research Product Managers (Pharmaceutical). We wish to appoint a graduate to assist the Senior Research Product Manager (Pharmaceutical) in these duties which require liaison with technical staff in Research and many other departments including Marketing, Quality Control and Production and the use of modern control techniques.

If you have a formal qualification, preferably in pharmacy, pharmacology or chemistry, some relevant experience in the pharmaceutical industry, the ability to co-operate with staff of various disciplines and to communicate effectively - then, you are the candidate we seek.

Conditions of employment include contributory pension and profit earning bonus schemes. Help with relocation is available if appropriate.

Please write for application form to: T. W. Flower, Employment Manager (Technical),

The Boots Company Ltd.,
Station Street, Nottingham NG2 3AA.

896(A)

**ASSISTANT PROFESSOR
OF APPLIED MATHEMATICS
DEPARTMENTS OF PHYSIOLOGY AND
BIOSTATISTICS**

Responsibilities include teaching of statistics and the conduct of collaborative research in pulmonary physiology. Essential are competence in mathematical modelling and in experimental design and analysis. Familiarity with pulmonary biology and computing is desirable. Address inquiries to Dr Joseph Brain, Department of Physiology, Harvard School of Public Health, 665 Huntington Avenue, Boston, MA 02115. Harvard University is an Equal Opportunity/Affirmative Action Employer. 911(A)

**NATIONAL INSTITUTE FOR
RESEARCH IN DAIRYING
(University of Reading)
FEEDING AND METABOLISM
DEPARTMENT**

Applications are invited for a scientist to undertake routine supervision and control of nutritional experiments on lactating cattle and young stock. The person appointed will also be expected to contribute to the planning and interpretation of the trials, including some statistical analysis.

Pass degree, H.N.C. in animal production or animal nutrition with physiology or equivalent experience is required. Practical dairy farming experience, current driving licence, and some knowledge of statistics would be advantageous.

Appointment will be as Scientific Officer (£2,592 to £4,032) or Higher Scientific Officer (£3,745 to £4,976) including current pay supplements, according to experience. At least five years' relevant postgraduate research or other approved experience is required for appointment as H.S.O.

Application forms and further details are obtainable from the Secretary, N.I.R.D., Shinfield, Reading RG2 9AT. Quote reference 77/41. 891(A)

**THE MIDDLESEX HOSPITAL
MEDICAL SCHOOL
(University of London)
DEPARTMENT OF
NEUROLOGICAL STUDIES
RESEARCH ASSISTANT**

Applications are invited from graduates for the post of Research Assistant to assist in a variety of laboratory projects connected with research in cerebrovascular disease (strokes). Experience with physiological and/or biochemical techniques an advantage. The post is available for two years.

Salary, according to age and experience, within the range £3,354 to £4,212 per annum (including £450 per annum London Allowance).

Applications, including curriculum vitae and the names and addresses of two referees should be submitted to Dr M. J. G. Harrison, Department of Neurological Studies, Sir Jules Thorn Institute of Clinical Science, The Middlesex Hospital Medical School, London W1. 882(A)

**THE MASSACHUSETTS
GENERAL HOSPITAL**

An opening for a Research Associate is available starting July 1, 1978. M.S. or Ph.D. in Biochemistry or Cell Biology with research interest in any of the following areas: cell membrane changes in differentiation and malignancy; cell surface membrane synthesis, particularly glycoprotein synthesis; in vitro protein synthesis in mammalian systems; calcium absorption and Vitamin D metabolism; Vitamin A metabolism.

The Research Associate will be part of a new program in Gastrointestinal and Nutritional Research being established at the State University of New York in Buffalo. An opportunity is also available for qualified applicants for an associated academic appointment in the Department of Biochemistry. Please send résumé to: Dr Milton M. Weiser, Chief of G.I. and Nutrition, S.U.N.Y., at Buffalo, c/o G.I. Laboratories, Massachusetts General Hospital, Boston, MA. 02114. 928(A)

Research Associateships are available for

Theoretical Nuclear Physicists

to join the Theory Group at Daresbury whose fields of interest are nuclear, solid state and atomic and molecular processes.

At the Laboratory a major nuclear structure facility is under construction, based on a 30 MV tandem Van der Graaf, and work will soon begin on a purpose-built X-ray and ultraviolet source. An IBM 370/165 computer is installed at the Laboratory, and a computational science group has recently been established working mainly on the quantum chemistry area.

The successful applicants will be appointed at salaries between £2901 and £5155, the level at which an associate is appointed depending on age, ability and experience. There are also pay supplements of (a) £313.20 per annum and (b) 5% of total salary subject to a minimum of £130.50 per annum and a maximum of £208.80 per annum. Posts are normally available for a fixed term of three years and are superannuable.

Applicants, male or female, should possess a Ph.D. degree in theoretical nuclear physics, or expect to obtain one during 1978.

Closing date: 1 February 1978

Please write enclosing curriculum vitae, the addresses of two referees and quoting reference number DL/606/T to:

(663)A

SCIENCE
RESEARCH
COUNCIL

DARESBURY LABORATORY

Personnel Officer,
Science Research Council
Daresbury Laboratory,
Daresbury,
Warrington WA4 4AD.

LOTHIAN HEALTH BOARD

Applications are invited for the post of senior grade Biochemist in the Endocrine Unit/Immunology Laboratories in the Royal Infirmary of Edinburgh under the direction of Dr W. J. Irvine. Responsibilities will be primarily to ensure the efficient running of the routine immunology services pertaining principally to auto-immune disease, and for those endocrine laboratory services carried out in the Department, which principally involve in vivo and in vitro tests of thyroid function. Opportunities for research, especially in clinical immunology would be available in collaboration with projects sponsored by the M.R.C. and C.R.C.

Applicants should have a good Honours Degree, and preferably an M.Sc. Ph.D., or first part M.R.C. Path. Experience in immunology is desirable. Whitley Council Conditions of Salary Scale and service apply.

The salary scale is £4,437 to £5,697 plus a salary supplement of £312 per annum, plus Phase II supplement. National Health Service Superannuation Scheme is in operation.

Further particulars on application.

Applications, which should be typewritten, giving particulars of age, qualifications and previous experience, together with the names and addresses of two referees should be lodged with the Secretary, 11 Drumsheugh Gardens, Edinburgh EH3 7QQ, by January 12, 1978.

867(A)

PLANT BREEDER-GENETICIST

ASSISTANT PROFESSOR, available July 1, 1978. Candidates should be prepared to teach undergraduate Plant Breeding/Genetics, develop a graduate Plant Genetics Course, and establish a research programme in his/her own area of specialty. Research experience with corn genetics/breeding is desired. Applicants should send curriculum vitae, transcripts, and three letters of reference to: Dr Hugh Frick, Search Committee Chairman, Plant Science Dept., University of Delaware, Newark, Delaware 19711 before March 1, 1978.

The University of Delaware is an Affirmative Action Equal Opportunity Employer.

838(A)

UNIVERSITY OF NOTTINGHAM DEPARTMENT OF ZOOLOGY

Applications are invited for the post of POSTDOCTORAL RESEARCH ASSOCIATE. The work involves a study of protein reabsorption in the kidney of a lower vertebrate. Candidates should have an interest in electron microscopy, renal physiology and micro puncture techniques.

Salary £3,333 per annum.

Application forms returnable not later than January 11, 1978 from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD.

898(A)

MEDICAL RESEARCH COUNCIL RADIOBIOLOGY UNIT, HARWELL

SCIENTIST needed to work in a multi-disciplinary group to study the microscopic distribution of inhaled radioactive particles in the respiratory system of experimental animals in relation to radiation-induced carcinogenesis. Preference will be given to candidates who have several years of relevant post-graduate research experience.

The Unit also includes groups studying mutation, genetics, cytogenetics and

Applicants should hold a relevant good honours degree. Starting salary would normally be in the range £3,974-£5,219 according to age and experience. M.R.C. conditions of service would apply. Hostel accommodation for single, or housing for married people may be available. Applications, with curriculum vitae and names of two referees, should be sent to Administrator, M.R.C. Radiobiology Unit, Harwell, Didcot, Oxon. OX11 0RD. Ref. JV/6.

941(A)

UNIVERSITY OF MELBOURNE LECTURESHP (LIMITED TENURE) IN ANIMAL PRODUCTION in the FACULTY OF AGRICULTURE AND FORESTRY

Applications are invited for this position commencing March 1, 1978. The successful applicant will be required to give lectures within the courses of animal production to students in Agricultural and Veterinary Science. He will also be expected to develop a research programme in his field of interest.

An applicant with interest and experience in systems analysis and modelling in animal production is preferred, however, other interests of the section into which he could fit are ruminant nutrition, animal genetics and animal behaviour.

QUALIFICATIONS: Ph.D. or equivalent, with some postdoctoral experience will be preferred.

SALARY RANGE: \$A14,632 to \$19,262.

The position will be offered for a limited tenure of three years. Further information, including details of application procedures and conditions of appointment, is available from The Registrar, University of Melbourne, Parkville, Victoria, 3052, Australia. Applications referring to position 200 199 should be addressed to The Registrar and close on January 31, 1978. Conditions of appointment available from the Association of Commonwealth Universities (Appl), 36 Gordon Square, London WC1H 0PF.

956(A)

THE UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY LECTURESHP IN CORROSION ENGINEERING/ TEROTECHNOLOGY AND CORROSION SCIENCE

The Corrosion and Protection Centre has a large, varied research school, M.Sc. Courses in Corrosion Science and Terotechnology, an advisory service for industry and provides teaching at undergraduate level. Two appointments are to be made, with some preference for younger candidates (male or female), showing evidence of quality and versatility in the following general fields: (a) Corrosion Engineering/Terotechnology (b) Corrosion Science.

Research areas the Centre wishes to develop further include heat, mass and momentum transfer, design, monitoring, non-destructive testing, economics and the terotechnological approach quantitative modelling, modern experimental techniques, surface coatings and the anodic behaviour of aluminium. Experience in one or more of these subjects would strengthen an application. Commencing salary will be within the scale £3,333 to £6,655 per annum.

Application forms are obtainable from the Registrar, U.I.M.S.T., P.O. Box 88, Manchester M60 1QD, enquiries should be directed to Professor G. C. Wood, Corrosion and Protection Centre (Tel. 061-236-3311 Ext. 2012).

892(A)

FACULTY POSITION IN BIOCHEMISTRY UNIVERSITY OF ILLINOIS AT URBANA CHAMPAIGN

The Department of Biochemistry is seeking applicants for a tenure track appointment at the level of assistant professor or higher to begin August 1978. Applicants should be qualified to teach biochemistry courses at undergraduate or graduate levels. Only candidates who have demonstrated excellence in research and who are prepared to establish an active research program will be considered, preference will be given to those who have received graduate and post-doctoral training in strong research environments. The minimum salary at the assistant professor level is \$15,000 for a nine month appointment; salaries at higher ranks are negotiable. For full consideration, application material, including a curriculum vitae, and list of publications, a brief description of research interests and three letters of reference should be sent by February 1, 1978:

Professor Lowell P. Hager, Head,
Dept. of Biochemistry
University of Illinois
Urbana, Illinois 61801
Telephone: (217) 333 3945

The University of Illinois is an affirmative action/equal opportunity employer.

785(A)

ETH Zürich

The Swiss Federal Institute of Technology (ETH Zurich)

announces a new position for a

Professor of Geodesy

The new professor will be responsible for teaching and research in the fields of mathematical, physical and astronomical geodesy, satellite geodesy and geodynamics.

The candidate must have several years of demonstrated experience and capability in initiating and directing research. He must be willing and competent to provide instruction at all university levels. Special emphasis will be placed on close interdisciplinary cooperation between geodesy and geophysics in both teaching and research.

Applications should be sent with curriculum vitae and list of publications before April 30, 1978 to the President of the Swiss Federal Institute of Technology Zurich, Professor H. Ursprung, CH- 8092 Zurich/Switzerland.

862(A)

SWINBURNE COLLEGE OF TECHNOLOGY

(Melbourne, Australia)

LECTURER IN BIOPHYSICS (Contract Appointment)

Applications are invited from graduates with a relevant higher degree in physiology, clinical biophysics or biomedical engineering and with clinical and/or research experience in cardiovascular physiology. Teaching experience will also be considered in making the appointment.

The appointment will be by contract for three years duration including removal and repatriation expenses. Permanent appointment, during or at the expiration of the period, may be negotiated by mutual agreement.

The successful applicant will be involved in the undergraduate and postgraduate biophysics teaching programme with particular responsibility for the cardiovascular component of these courses. The successful applicant will also be encouraged to participate in an area of relevant applied research.

Swinburne College of Technology is a tertiary educational institution affiliated with the Victoria Institute of Colleges. The Department of Physics is a member department of the Faculty of Applied Science, and has academic responsibility for undergraduate courses in biophysics and instrumental science together with postgraduate programme in biophysics, biomedical instrumentation and instrumental science.

Salary: Lecturer I \$A14,631 to \$16,748; Lecturer II \$A17,145 to \$19,261 p.a.

Applications close **February 18, 1978**. Further information about the position, conditions of employment and application procedure may be obtained from the Association of Commonwealth Universities (Appts), 36, Gordon Square, London WC1H 0PF. 920(A)

FRESHWATER BIOLOGICAL ASSOCIATION WINDERMERE LABORATORY

Applications invited from biologists for two-year contract from April 3, 1978 to work on development of samplers for macro-invertebrates in rivers. Good honours degree essential, preferably Ph.D., experience in river invertebrate taxonomy, field sampling and analysis of numerical data desirable. SCUBA diving experience useful. Post equivalent to Scientific Officer in Civil Service. Gross salary within range £3,078-£4,048. Full details and application forms from Secretary, Freshwater Biological Association, The Ferry House, Ambleside, Cumbria LA22 0LP (Tel: 096 62 2468). Closes February 6, 1978. 942(A)

THE GOVERNMENT OF THE SYRIAN ARAB REPUBLIC ALEPPO UNIVERSITY

ALEPPO UNIVERSITY HOSPITAL

Invites applicants for posts in Anaesthesia vacant 1977/1978. Qualifications: F.R.C.S. one. In addition to five years experience.

Salary: £8,000 to £10,000 per annum; plus £1,350 to £1,700 accommodation allowance per annum.

- One month paid holiday per annum
- Return tickets to country of residence at the end of contract, also for wife and two children.
- Contract for one year renewable.

Please write for full details to:

The Rector
University of Aleppo
Syrian Arab Republic 864(A)

UNIVERSITY OF MELBOURNE CHAIR OF METEOROLOGY (Foundation Appointment)

Applications are invited for appointment to the newly established Chair of Meteorology.

SALARY: \$A31,248 per annum.

Further information, including details of application procedure, superannuation, travel and removal expenses, housing assistance, and conditions of appointment, is available from the Registrar. All correspondence (marked "Confidential") should be addressed to The Registrar, University of Melbourne, Parkville, Victoria 3052, Australia. Information also available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on **March 31, 1978**. 937(A)

UNIVERSITY OF LEICESTER RESEARCH ASSISTANT IN CHEMISTRY

An S.R.C. Postgraduate appointment is available for a suitable candidate to study "The Aqueation of Alcohols and Sugars using N.M.R. and Infrared Spectroscopy".

The work is a combined study with Professor M. C. R. Symons and Dr W. Derbyshire of Nottingham University, and the initial salary will be up to £3,333 a year, starting as soon as possible.

For details, please contact Professor M. C. R. Symons, Department of Chemistry, The University, Leicester LE1 7RH. 872(A)

UNIVERSITY OF ULM, WEST GERMANY LABORATORY OF IMMUNOLOGY, DEPARTMENT OF MICROBIOLOGY POSTDOCTORAL RESEARCH ASSISTANT IMMUNOCHEMISTRY/ BIOCHEMISTRY

Immunologists are invited to apply for a postdoctoral research assistantship to work on a project concerned with cell interactions in the immune response with special reference to humoral mediators. The position is at least for three years, will be open January 1, 1978 or later and has a salary according to qualification and experience (£12,900 to £13,600). Candidates should preferably have a Ph.D., a background in immunochemistry is essential. Applications including curriculum vitae, a description of research experience, relevant reprints and the names and addresses of two referees should be sent to Dr H.-D. Flad, Laboratory of Immunology, Department of Microbiology, University of Ulm, P.O. Box 4066, D-7900 Ulm, West Germany. 868(A)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (University of London)

Denmark Hill London SE5 8RX

Applications are invited for two positions in a busy multi-disciplinary Unit:

- 1 A RESEARCH ASSISTANT, who should be a graduate microbiologist or have equivalent qualifications or experience, to study host defence mechanisms in chronic liver disease. The appointment is for one year in the first instance.
- 2 A RESEARCH FELLOW, preferably post-doctoral with experience in cell membrane biology, immunochemistry or protein biochemistry, to work on human liver cell surface antigens. The appointment is for three years in the first instance.

Salaries and conditions of service according to the University of London Research Assistant's IA/IB scales.

Further details from: Dr T. G. McFarlane, Principal Biochemist, The Liver Unit, Applications to the Secretary of the Medical School not later than January 21, 1978. 919(A)

ECOLOGIST-ASSOCIATE DIRECTOR UCLA

Applications are invited from highly qualified ecologists to become Chief of Division of Environmental Biology and Associate Director of the Laboratory of Nuclear Medicine and Radiation Biology. The position carries a joint appointment, presumably at the full professor level, in the Department of Biology, and undergraduate and graduate teaching responsibilities. Research interests should be in quantitative ecology and applicants should be interested in resolving environmental problems related to energy technologies because the Laboratory's research is funded primarily by the Department of Energy (formerly E.R.D.A.).

Send letters of inquiry or application, including curriculum vitae, description of research and teaching interests, and names and addresses of three references before February 15, 1978 to Director's Office, Laboratory of Nuclear Medicine and Radiation Biology, University of California, 900 Veteran Avenue, Los Angeles, California, 90024. An equal opportunity/affirmative action employer. 902(A)

POSTDOCTORAL POSITION ELECTROPHYSIOLOGY— PHARMACOLOGY

Available immediately, N.I.H. funded. To study nerve cells in tissue culture using voltage clamp and fluctuation analysis with on line computer facilities. Experience in electrophysiology with micro-electrodes essential, computer programming and biophysical orientation desirable. Send CV and references to Dr Fred Sachs, Dept. of Pharmacology, S.U.N.Y., Buffalo, NY 14214, U.S.A. An Affirmative Action/Equal Opportunity Employer. 834(A)

PHARMACOLOGY

We require a graduate with up to 3 years relevant experience to work on the development of drugs for certain cardiovascular diseases. The successful applicant would work within a small team reporting directly to the Team Leader.

The Research and Development Laboratories are situated in the pleasant surroundings of the East Midlands and the position attracts benefits such as flexible working hours, help with relocation expenses in suitable cases, etcetera.

If you are interested please contact Bryan Johnston, Fisons Limited, Pharmaceutical Division, Research and Development Laboratories, Bakewell Road, Loughborough, Leics. LE11 0QY. Telephone 0509 66361 quoting reference number 539R.

945(A)

UNIVERSITY OF MALAWI CHANCELLOR COLLEGE

Applications are invited for the post of
LECTURER IN PHYSICS

tenable as soon as possible. Applicants should have at least a good honours degree in Physics or Electronics. Preference will be given to candidates with a higher degree and whose research interest is in the field of Physics of materials, applied acoustics, solar energy or electronics. Teaching, research and industrial experience would also be an advantage. The appointee will be expected to teach at all levels of the four year general degree programme.

Salary range: K2,809 to K4,714 p.a. The British Government may supplement salary in range £3,450 to £3,864 p.a. (sterling) for married appointees and £2,184 to £2,568 p.a. (sterling) for single appointees (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. If no British Government supplementation available, university will pay K720 p.a., taxable in Malawi. Family passages, various allowances, biennial overseas leave, gratuity, housing.

Detailed applications (2 copies) should be sent air mail by January 23, 1978 together with curriculum vitae and naming 3 referees to Registrar, University of Malawi, University Office, P.O. Box 278, Zomba, Malawi. Applicants resident in U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address.

885(A)

UNIVERSITY OF WISCONSIN-PARKSIDE INDUSTRIAL HYGIENIST

Tenure-track faculty position, September 1978. New baccalaureate program in Industrial and Environmental Hygiene. Rank and salary open and commensurate with experience and qualifications. Candidates must have training and professional experience in Industrial Health and be eligible for board certification. Board certification in Industrial Hygiene is desirable. Appropriate doctoral degree preferred. Well qualified persons with a masters degree may also be considered. Appointee will teach undergraduate courses in Industrial Hygiene, including externships, advise students and participate in university, community and professional activities. We seek candidates who can provide leadership, have strong commitment to teaching, and are involved in research. All replies confidential. Inquiries and applications with three letters of reference to Dr Surinder P. Datta, I.E.H.A. Committee, University of Wisconsin-Parkside, Kenosha, WI 53141 U.S.A. (414-553-2469), by February 20, 1978. An affirmative action/equal opportunity employer. 716(A)

UNIVERSITY OF OXFORD Microbiology Unit DEPARTMENT OF BIOCHEMISTRY POSTDOCTORAL

RESEARCH ASSISTANT—Ref. B14

There is a vacancy for a postdoctoral biochemist or microbiologist to work on bacterial sporulation. The appointment, which will be for one year in the first instance, on the scale £3,333 to £5,627, may be extended for a further period of two years and there is provision for U.S.S. membership.

Applications, which should include relevant details and the names of two referees, should be sent before February 28, 1978, to Professor J. Mandelstam, Microbiology Unit, Dept. of Biochemistry, South Parks Road, Oxford OX1 3Q.

DEPARTMENTAL DEMONSTRATORSHIP—Ref. B15

It is proposed to appoint a Departmental Demonstrator from October 1, 1978. The salary will be on the scale £3,333 to £3,833, according to qualifications and experience and with membership of U.S.S. The appointment is for a period not exceeding 3 years. The successful candidate will be expected to take part in departmental teaching and to conduct his or her own research.

Applications (3 copies) including the names of two referees, should be sent to: The Administrator, Department of Biochemistry, South Parks Road, Oxford OX1 3QU not later than February 28, 1978. 863(A)

OXFORD UNIVERSITY

THE UNIVERSITY:
ST. EDMUND HALL

and

ST. HUGH'S COLLEGE

Nuffield Medical Research Fellowship 1978

Applications are invited for a Nuffield Medical Research Fellowship to be held in conjunction with a Junior Research Fellowship at one of the above colleges. The Fellowship will be tenable for two years from April 1, 1978 (or a later date by agreement) in one of the clinical medical departments of the University and be renewable for a third year. Scale of stipend will be £4,665-£5,643 p.a. if medically qualified and £3,333-£4,190 p.a. if not.

Further particulars of the Fellowship may be obtained from The Secretary, Board of the Faculty of Clinical Medicine, 1A Observatory Street, Oxford OX2 6EW, to whom applications, together with the names of two referees should be sent by January 31, 1978. 943(A)

WELSH NATIONAL SCHOOL OF MEDICINE

(University of Wales)

Applications are invited for the post of
POSTDOCTORAL

RESEARCH IMMUNOLOGIST

at the K.R.U.F. Institute of Renal Disease, Cardiff. This post is available under a Programme Grant from the M.R.C. It will be for one year in the first instance and may be renewable annually thereafter for up to three years; commencing salary, according to qualifications and experience, in the region of £4,600. The successful applicant may initiate his own programme of research but will be expected to assist in the immunological evaluation of kidney recipients and the assessment of new immunosuppressive regimes. Ample laboratory space is available within the Institute. Applications, which should take the form of a brief curriculum vitae with the names and addresses of two referees, should be sent to the Registrar, Welsh National School of Medicine, Heath Park, Cardiff, quoting reference No. M6/7/14. Further information available from Mr John K. Salaman, M.Chir., F.R.C.S., tel. no. 0222 492233 ext. 450, 870(A)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PHYSICAL CHEMISTRY POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Postdoctoral Research Assistantship in the Department of Physical Chemistry for research into aspects of two-photon absorption spectroscopy, particularly the study of Inverse Raman Spectra. Experience in the development and construction of high power visible lasers would be of value, as would a background in high resolution molecular spectroscopy and/or electronics. The post is tenable for a period of one year, but there may be a possibility of an extension for a second year. The initial salary will be within the range £3,333 to £3,547 per annum according to qualifications and experience (appointments outside this range may also be considered) plus U.S.S. benefits.

Applications, stating age, academic qualifications and experience, together with the names of two referees, should be submitted to Dr W. J. Jones, Department of Physical Chemistry, Lensfield Road, Cambridge CB2 1EP. 933(A)

FIELD STUDIES COUNCIL

TUTOR in ECOLOGY at Juniper Hall Field Centre, Dorking, Surrey. Single, good degree in biology or other appropriate science, botanical interest and experience of lowland terrestrial ecosystems and knowledge of French or German an advantage. Educ. qualif. desirable. Salary £1,944 by 84 by 84 to £2,112 plus free board and lodging. Appointment February 1978 if possible. Closing date for applications January 20, 1978. Further details and application forms from The Director, Field Studies Council, Preston Montford, Montford Bridge, Shrewsbury SY4 1HW. 914(A)

THE CITY UNIVERSITY DEPARTMENT OF CHEMISTRY Lecture Course on THE FLAMMABILITY AND BURNING OF SOLID MATERIALS

A course of postgraduate or post-experience lectures, arranged by Professor J. H. Burgoyne, will be given from March 6-8, 1978. This Course will be concerned with the mechanisms of ignition, burning and retardancy of solid materials and will attempt to relate this understanding, through testing and legislative control, to the practical use of these materials.

Further details may be obtained from the Secretary of the Chemistry Department, The City University, St John Street, LONDON EC1V 4PB. Telephone 01-253 4399 (extension 532). 603(D)

NATO ADVANCED STUDY INSTITUTE Interlinking of Computer Networks

BONAS, FRANCE August 28th to September 8th, 1978

This Institute offers a two-week structured programme designed to investigate in depth the problems inherent in the transmission of data between and through computer networks.

Acknowledged experts drawn from the international scientific community will provide extensive reviews of the technical and organisational issues involved. The lectures will be supported by tutorial discussions and work-shops.

Approximately sixty scientists will be selected to attend the Institute.

A certain number of supporting NATO fellowships are available to participants from membership countries.

Fellowships will be considered on the basis of individual merit and fair distribution among membership countries.

Lecturers include:

J. W. Burden (U.K.), V. Cerf (U.S.A.), D. W. Davies (U.K.), H. J. Helms (Italy), P. Kirstein (U.K.), F. F. Kuo (U.S.A.), G. Le Moli (Italy), T. Pyke (U.S.A.), E. Raubold (Germany), H. Zimmerman (France).

Forms of application are available from:

Dr K. G. Beauchamp, Director, Computer Services Dept., University of Lancaster, Bailrigg, Lancaster, U.K. Telephone: (0524) 65201

The deadline for receipt of completed applications is March 1st 1978. 901(K)

LOUGHBOROUGH UNIVERSITY OF TECHNOLOGY

GEL FILTRATION AND ELECTROPHORESIS

A one week residential course from April 3 to 7, 1978, on the theory and applications of gel filtration, ion-exchange, electrophoresis on cellulose acetate, polyacrylamide and other media, isoelectric focusing and isotachopheresis, affinity and hydrophobic chromatography, and immunoelectrophoretic techniques. There will be ample opportunities for course members to run their own samples and discuss problems with representatives of leading manufacturers in these fields. The course is suitable both for beginners and for more advanced workers.

The course fee is £100 including accommodation. Applications and further information from Dr J. N. Miller, Department of Chemistry.

Next course in the series:
Spectrofluorimetry and Related Methods.
July 3 to 4, 1978.

Loughborough Leicestershire
883(D)

FELLOWSHIPS

RUHR-UNIVERSITY BOCHUM (Germany)

Applications are invited from suitable qualified candidates for a

RESEARCH FELLOWSHIP IN CELL PHYSIOLOGY

The position, which is financially supported by the Deutsche Forschungsgemeinschaft (SFB 114) is connected with the Department of Cell Physiology, Ruhr-University Bochum. The successful candidate would be expected to work in one of the following fields: **Electrophysiology of skeletal or heart muscle cells or synapses, excitation contraction coupling, pores in artificial membranes.**

The salary ranges from 1,700 to 3,500 DM per month, after deductions (depending on qualification, age, marital status etc.). Travel expenses can in addition be paid.

The appointment will be for one year, it can be prolonged for up to three years.

Applications including a curriculum vitae and the names of two referees should be sent to

Prof. H. G. Glitsch or Prof. H. Ch. Lüttgau
Department of Cell Physiology
Ruhr-University Bochum
P.O. Box 102148
D-4630 Bochum 1, F.R.G. 875(E)

THE UNIVERSITY OF LEEDS DEPARTMENT OF MECHANICAL ENGINEERING I.C.I. RESEARCH FELLOWSHIP ON BEARING INFLUENCED ROTOR DYNAMICS

Applications are invited for a 3 year, I.C.I. sponsored, Research Fellowship. The work involved represents a co-operative project on bearing influenced rotor dynamics between I.C.I. and the University of Leeds; it will include the development of computer programs to predict the vibrational characteristics of rotor/bearing systems, and the application of the programs to particular problems of interest to the sponsor. Experience in system dynamics and/or bearing analysis would be an advantage. The Research Fellow, who will be based at the University of Leeds but will also carry out investigations in industry with I.C.I. staff, may be a candidate for a higher degree, or a Postdoctoral Fellow. The salary will be on either the 1A Scale for Research and Analogous Staff £3,333 to £5,627; but in the case of a candidate with exceptional qualifications and experience a higher figure may be negotiable.

Applications, and further enquiries, should be directed to Professor D. Dowson, Department of Mechanical Engineering, The University, Leeds LS2 9JT (Tel. 0532-31751 ext. 254). 950(E)

UNIVERSITY OF EAST ANGLIA Norwich POSTDOCTORAL FELLOWSHIP (S.R.C.)

in the School of Biological Sciences for three years to investigate a hybrid zone in an alpine grasshopper. This will involve a major study of allozyme variation, which will be complemented by genetical and ecological studies. Initial salary in the range RA (1A) £3,333 to £3,761.

Applications with curriculum vitae and naming three referees as soon as possible to Dr G. M. Hewitt, School of Biological Sciences, University of East Anglia, Norwich NR4 7TJ, from whom further information is available. 815(E)

SENIOR RESEARCH FELLOW IN ATOMIC/MOLECULAR PHYSICS

The University of Maryland and the National Bureau of Standards in Washington, D.C. are announcing a one year fellowship for a senior research scientist to pursue research at the N.B.S. Synchrotron Ultraviolet Research Facility (S.U.R.F.). The S.U.R.F. fellow will hold an appointment in the Institute of Physical Science and Technology at the College Park Campus of the University of Maryland. In addition to his research activities at S.U.R.F., the appointee will interact with the faculty and students at the University, principally through lectures and seminars.

Applications are now being accepted for the academic years 78-79 and 79-80, with detailed schedule to be negotiated. Salary and faculty rank will be commensurate with current position. We are initially seeking an individual interested in pursuing atomic/molecular physics at S.U.R.F. Experience in the use of synchrotron radiation and/or photoelectron spectroscopy of gases will be considered particularly valuable for the 78-79 appointment. Later appointments may be in other fields.

Send résumé, desired starting date and research plans to:

Prof. Joseph Silverman
Institute for Physical Science and
Technology
University of Maryland
College Park, Maryland 20742 954(E)

UNIVERSITY OF MELBOURNE JUNIOR RESEARCH FELLOW DEPARTMENT OF MATHEMATICS

Applications are invited for a post-doctoral Junior Research Fellowship in the Department of Mathematics from candidates with suitable qualifications in statistical mechanics. The Fellowship is funded by an ARGC grant for a project titled "Statistical Mechanics of Liquids and Liquid-Solid Interfaces". The appointment is for a period of up to two years and includes a contribution towards travel expenses.

SALARY: \$A12,160 to \$A13,390 per annum.

The appointment will commence as soon as possible.

Enquiries may be directed to Dr E. R. Smith, Department of Mathematics.

Further information, including details of application procedure is available from The Registrar. Applications referring to Position Number 618333 should be addressed to The Registrar, University of Melbourne, Parkville, Victoria, Australia, 3052. Closing date for applications is February 28, 1978.

889(E)

DEPARTMENT OF MICROBIOLOGY DALHOUSIE UNIVERSITY HALIFAX, NOVA SCOTIA, CANADA

Applications are invited for POSTDOCTORAL FELLOWSHIPS to study viral pathogenesis with special emphasis on the role of interferon. Fellowships beginning July 1, 1978, are available for a period of two years with an initial stipend of \$12,720 per annum. Candidates should have research experience in the field of animal virology, preferentially with an interest in the biochemistry of nucleic acid biosynthesis. Applications, consisting of curriculum vitae and names of two referees, should be sent not later than March 30, 1978 to Dr K. R. Rozee, Professor and Head, Department of Microbiology, Faculty of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada. 932(E)

JESUS COLLEGE, OXFORD

The College invites applications from men and women for a Junior Research Fellowship open to candidates intending to pursue research in any branch of Chemistry and tenable for 2-3 years from October 1, 1978. Further particulars may be obtained from The Principal, Jesus College, Oxford OX1 3DW, to whom applications must be sent no later than January 31, 1978. 897(E)

FOURTH EMBO ANNUAL SYMPOSIUM

3rd-7th May, 1978

"MOLECULAR NEUROBIOLOGY"

The Symposium will be held at the European Molecular Biology Laboratory, Heidelberg, which is to be opened on Friday, 5th May, by the President of the Federal Republic of Germany.

Topics covered at the Symposium will include neuroreceptors, neuropeptides, development of the nervous system, neutral cytoskeletons, higher brain functions.

Plenary Sessions: The speakers will include

B. Boycott (England), D. Bray (England), M. Brownstein (USA), J.-P. Changeux (France), M. Cuénod (Switzerland), G. Edelman (USA), S. Fuchs (Israel), D. Gilbert (England), J. Glowinski (France), B. Hamprecht (Germany), E. Helmreich (Germany), J. Heuser (USA), T. Hökfelt (Sweden), J. Jansen (Norway), M. Lazdunski (France), R. Levi-Montalcini (Italy), U. Littauer (Israel), J. Massoulié (France), E. Neher (Germany), Ph. Nelson (USA), L. Olson (Sweden), W. Reichardt (Germany), M. Schramm (USA), W. Singer (Germany), J. Stinnakre (England), N. Strausfeld (Germany), L. Terenius (Sweden), H. Thoenen (Switzerland).

Poster Sessions

In addition to the plenary sessions poster sessions will be held each day during the Symposium to allow participants to present contributions on topics related to or complementing the plenary sessions as well as on recent technical developments.

Participation

Applications should reach Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 102240, 69 Heidelberg 1, West Germany, before the end of February. They should include a curriculum vitae, an indication of the applicant's scientific background, and current research interests. Participants who wish to contribute a poster should submit a title and an abstract of 1-2 pages. A registration fee of DM 80 will be charged. Bed and breakfast and accommodation (DM 20-40 per day) in the vicinity of the EMBL will be arranged by the Symposium secretariat. Participants will be responsible for their living and travel expenses.

THE UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY

Chemical Society Macromolecular Group
Society of Chemical Industry Plastics and
Polymer Group

Polymeric Biomedical Materials

A Symposium to be held in Manchester on
Tuesday and Wednesday 18th and 19th April 1978

The aim of this Symposium is to inform polymer scientists of the requirements which polymeric materials must fulfil in biomedical applications but it may also be of interest to medical scientists by indicating how improved materials might be developed which would meet requirements better than those currently available.

The Introductory Lecture will be given by Professor D. F. Gibbons (Case-Western Reserve University, USA). Subsequent sessions will discuss *Polymers for Tissue Replacement* (Speakers: Mr D. Annis (Liverpool), Professor M. Braden (London), Dr G. W. Hastings (Stoke), Mr G. P. Pearson (Bradford), Dr G. D. Winter (Stanmore)); *Polymers as Biomedical Materials* (Professor A. Bantjes (Holland), Professor E. P. Goldberg (Florida), Professor N. Graham (Strathclyde), Dr A. Rembaum (California)); and *in vitro Testing of Polymers for in vivo Applications* (Dr G. Braun (Ruhchemie AG), Dr J. M. Courtney (Strathclyde), Dr W. S. Haworth (Oxford)).

Further details may be obtained by application to
The Registrar, UMIST, P.O. Box 88,
Manchester M60 1QD

HERIOT-WATT UNIVERSITY

DEPARTMENT OF CHEMISTRY

S.R.C. POSTDOCTORAL RESEARCH ASSOCIATESHIP

Applications are invited for a Post-doctoral Research Associate to work on the development and application of ¹⁸¹Ta Mössbauer spectroscopy. The successful applicant is likely to be a chemist or physicist with an interest in and preferably experience of research in solid state science and/or Mössbauer spectroscopy.

The post is tenable for two years on salary range 1A (up to £3,547 p.a. plus U.S.S. membership in the first instance).

Applications, with curriculum vitae and the names of two referees, should be sent as soon as possible to Dr M. J. Tricker, Department of Chemistry, Heriot-Watt University, Edinburgh EH14 4AS from whom further information may be obtained.

905(O)

QUEEN MARY COLLEGE

University of London

CHEMISTRY DEPARTMENT

Applications are invited for a

POSTDOCTORAL

RESEARCH ASSISTANTSHIP

supported by Hoffmann-La Roche to investigate the structure of caroteno-proteins by the synthesis and recombination of modified carotenoids and a study of the physical properties of the products. Salary in range £3,805 to £4,233 p.a. (under review). Please send curriculum vitae and names of two referees to The Registrar (N), Queen Mary College, Mile End Road, London E1 4NS.

890(P)

GRADUATE ASSISTANTSHIPS

are available for well qualified pre-doctoral students in Geophysical Fluid Dynamics, particularly in the area of computer and laboratory modelling of variations in the climate. A strong background in mathematics and physics is needed but prior training in a geophysical discipline is not necessary. Minorities and women are especially encouraged to apply. Write to Director, Geophysical Fluid Dynamics Institute, 18 Keen Building, Florida State University, Tallahassee, Florida 32306.

TTF and TCNQ

Components for conductivity

Tetrathiafulvalene (TTF) and several other tetrathioethylenes were originally investigated as possible electron-rich olefins.¹ It was quickly realized that the electrochemistry of TTF was by far the most interesting aspect of the compound. Wudl *et al.*^{2,3} discovered that TTF formed an exceptionally stable radical cation complex with chlorine (TTF⁺Cl⁻) which exhibited an unusually high electrical conductivity.

TTF

TCNQ

7,7,8,8-Tetracyanoquinodimethane (TCNQ) was first studied for its ability to form radical anions.^{4,5,6} Since then, many practical applications have been discovered. For example, TCNQ is used in the:

- 1) colorimetric determination of free radical precursors⁷
- 2) visualization of certain nitrogen and sulfur compounds on thin-layer and paper chromatograms^{7,8}
- 3) replacement of MnO₂ in aluminum solid electrolytic capacitors⁹
- 4) construction of heat-sensitive resistors¹⁰
- 5) induction of radical polymerizations (in combination with *N,N*-dimethylaniline *N*-oxide)¹¹
- 6) construction of ion-specific electrodes.^{12,13}

It was the ability of TCNQ to form radical anions that prompted Cowan¹⁴ to combine it with the electron donor TTF. The resulting charge-transfer complex was found to contain TTF and TCNQ in a 1:1 ratio.

This complex behaves electrically and optically like a one-dimensional metal at room temperature. It has one of the highest electrical conductivities known for an organic compound, being highly anisotropic along an axis defined by the colinear stacks of TTF and TCNQ.¹⁵ Since there was

some controversy over the exact value of the conductivity, a study was performed to determine if the chemical purity of the components affected the electrical conductivity of the complex.¹⁶ The workers concluded that crystal perfection rather than chemical purity was the factor chiefly responsible for determining the degree of conductivity. Major research efforts are currently in progress to better understand and find applications for the unusual properties of the TTF/TCNQ complex.^{17,18,19}

Aldrich has offered TCNQ for many years. Now we also offer TTF! With the ready availability of these "components for conductivity," the TTF/TCNQ complex is more accessible for further studies.

starting from scratch

**Design Council
Award 1977****TWO YEAR
GUARANTEE**

Gamma counter of the year?

When we designed the Wilj System 2001 we thought about performance, flexibility, reliability, easy operation, fast service and low cost.

The Design Council Award is some evidence of our success, and we back up that accolade with a solid 2 year guarantee.

You can buy the Gamma Counter alone for single sample assays, then add the 100 sample automatic changer with the printer or other data-processing options, as assay demand increases.

If you are looking for larger capacity, consider installing two or more Wilj systems. It can work out cheaper and faster, and you won't have all your RIA eggs in one basket. The word is flexibility.

Our brochure spells-out the details of the 2001. Send off for your copy now and find out exactly what all the fuss is about.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

nature Book Service

To obtain one or more of the titles listed on page xiv (all recently reviewed in *Nature*), complete and return the order form (or a photocopy) or write giving full details. Orders must be accompanied by a cheque (personal or otherwise), postal order or money order for the total cost. **Postage (surface mail) and packing is free.** Payment from overseas may be made in any currency at the prevailing exchange rate. Cheques should be made payable to **Nature**.

12 January 1978

Vietnam—an inexpensive form of help

RECENTLY Dr Alastair Hay, a nutritional biochemist who has written frequently in our news pages over the past few years, went on a visit to Vietnam with financial support from *Nature*. The first of his three reports on postwar Vietnam appears in this issue. It comes at a time when Vietnam finds itself yet again involved in conflict, this time with its neighbour Kampuchea (Cambodia) over borders, although there is as yet no clear indication that the skirmishes will have a serious effect on redevelopment within the war-weary nation.

The scientific tradition has not been particularly strong in the past in this part of Asia; certainly not as strong, say, as in the Indian sub-continent or China. True, no country has ever had so much sophisticated technology dropped on it or so many large-scale and sinister 'experiments' performed in it, such as weather modification, the automated battleground, and defoliation. But all of this is of little value in postwar days and if Vietnam is to emerge as a healthy nation it will have to use its relatively few scientists intelligently and to give science a high priority in development plans. This it seems to be doing quite well.

But there are pitfalls along the way. The view has been expressed that since the army of a relatively small country was able to contain all the fury of the United States so might Vietnam's small band of scientists do remarkable things on their own. This is not, it should be said, a view expressed by the scientists themselves. But it has a certain superficial appeal and could do a lot to harm the development of good science within Vietnam. For there are already forces at work trying to make Vietnam stand on its own

feet economically—the USSR, the largest supplier of aid to Vietnam and also the country with the largest influence, is cutting back its aid in a drive to make the country more self-sufficient. If scientists, too, sense that they are being required to go it alone they could face grave difficulties.

For what Vietnamese scientists clearly need more than anything else—more even than gifts of expensive equipment, more than expressions of appreciation from politicians—is normal scientific relations with the rest of the world. This would mean a much greater flow of books and journals into the desperately under-equipped libraries and, even more, a flow of people into and out of Vietnam. And it is particularly important that Vietnamese scientists should not feel constrained to establish good relationships only with those in the West whose political position on the war was a matter of public knowledge. For sure, a small number of such scientists have done a lot of good for Vietnamese science, and have helped to raise Western awareness of the Vietnamese plight, but now the net has to be cast much broader to take in anyone who might make a significant contribution, whether or not they are politically committed.

The largest obstacle to the development of science in Vietnam is an information barrier—not deliberately erected but just a natural consequence of war and isolation. It needs a concerted effort by all scientists of good-will to dismantle it. In Britain the Ministry of Overseas Development, the British Council and the Royal Society are all in a position to make a contribution to this relatively low-cost way of stimulating science. □

Holiday diary

January 7. To the misnamed Science Museum at South Kensington with the children. After the tide of irrationality and anti-science of the past decade, good to see the place filled with youngsters still interested in logical ways of thinking. Sure, most of them will remember the place mainly for the knobs to press and the handles to turn, but even so something probably rubs off on them of fascination for machinery and orderliness. 'Please keep off the moon', says the lunar exhibit. Lasers all the rage these days; one on the roof of the Royal Academy, of all places, to advertise a show there; one used at Covent Garden in Tippett's new opera; so off to top floor to see Science Museum's own Laser exhibition, even though pricey to go in (75p). Quaint

and dubious distinction between 'laser light' and 'ordinary light' on a display. Lots of good honest mundane uses of lasers—communication, pipe laying, surveying, cutting cloth and so on. Striking Russian holograms of museum-pieces. Children a bit bored because not many buttons to press. Quite a surprise to get to the end of the show so quickly, though children clearly mildly relieved as they can get back to the working models. Holograms on sale at the exit, for £12.50 each. But what do they portray? 'That's Paul Revere', says man at desk. 'Who?', says my neighbour. 'Haven't you anything else?', he asks, 'Yes—we have all the astrological signs too'. Rapid exit to the irrational world. □

Disaster relief needs more research

John Rivers, of the London Technical Group, argues that more research on disaster relief is needed if funds are to be used effectively*

THE CYCLONE and tidal wave that struck Andhra Pradesh in November last year killed about 30,000 people. But it devastated half a million, and made 2,000,000 more homeless. In the previous two years cyclones had also struck the state, ruining the harvest and leaving farmers deeply in debt. So, at the start of 1978, Andhra Pradesh is poised between recovery and a collapse that would make it rank alongside Sahel and Ethiopia in the vocabulary of suffering.

The immensity of this disaster has not, however, been reflected in the interest shown in it by the rest of the world. It has been a minor story, a few column inches on an inside page, while UK headlines have concentrated on the firemen's strike and the value of the dollar. Few seem to care about Andhra Pradesh. USAID figures, issued one week after the cyclone, estimated that aid from the international community was less than 1% of the \$675,000,000 of damage done. In Britain, the Disaster Emergency Committee's Appeal was a flop, raising only a quarter of the desired million pounds.

The public's lack of interest may not be surprising. The media have produced an unending diet of catastrophe. And the public may be becoming cynical about the usefulness of aid. This would be understandable, given such misdirected aid as the sending of skis to flood victims or brassieres to the starving, which rightly get pilloried in the press. But though newsworthy such events are of minor importance. The major waste in relief funds is more subtle.

In the rare cases where disaster research has been undertaken, the research has exposed the mythological basis of traditional relief. Inoculation campaigns, for example, have been an expensive component in all flood relief programmes since the war, as they were in Andhra Pradesh. Yet epidemiological studies by the Centre for Disease Control, Atlanta, Georgia, have revealed them to be unnecessary and ineffective. The vaccines are not as efficient as is often supposed, and they take about 10 days and two or more inoculations to give a reasonable level of immunity. Moreover the dilution of sources of contamination is much greater, and disruption of water supplies much less in disasters than has hitherto been supposed. So the alternative of simple symptom-reporting systems and intensive investigation of supposed outbreaks, is, as the Guatemalan experience has shown (Romero, A. B., Cobar, R., Western, K. A. & López, S. M., *Disasters* 2, 19-26; 1978) cheaper and more efficient than the fabulously expensive vaccination campaigns that hypnotise relief agencies. The money wasted on such unnecessary flummery is unlikely to have saved lives in Andhra Pradesh; almost certainly it cost lives by diverting scarce resources from more useful action. Other examples of such re-evaluation could be cited, even more await study. As long as disaster aid is less than adequate there will be a need for a science of relief, for a disaster technology.

In the days following the Bengal cyclone in 1971, the London Technical Group (LTG) was started by a group of postgraduate students anxious to encourage the growth of this field. Our first inclination was to initiate a dialogue between aid administrators and academic scientists. It was a twofold failure. First, most academic scientists had a crucial problem in their lack of practical experience of disaster situations. Scientific expertise, no matter how exalted, could be proved inappropriate by peculiarities, often

social, of the population affected by the disaster. Food aid, for example, is a fairly unchallenged item of disaster relief, being sent on the premise that if infantile malnutrition is endemic in good times, it must reach horrific proportions following a disaster. In Andhra Pradesh, as in the Bengal Cyclone, this is unlikely: the sea surge itself killed the very young and the very old, so that the malnourished and vulnerable died, and only the fittest survived. The aid sent presupposed high levels of infantile malnutrition; they are probably lower than ever before.

In housing too the social factor can negate apparently good logic, and the whole field of disaster shelter is littered with clever designs that nobody wants as homes. There is a considerable body of evidence that the best choice for disaster shelter is to use local materials and local labour to rebuild. The result is acceptable, familiar, and morale boosting (Davies, I, *Disasters* 1, 82-90; 1977). Most architects and designers, however, seem to be unaware of these constraints, and find ready sponsors for their designs in government and charitable disaster relief agencies.

This pattern is repeating itself in Andhra Pradesh where the state government and some voluntary agencies are erecting pre-stressed concrete buildings ill-suited to the climate but enough of a status symbol to lead to consumer resistance against the modifications of traditional buildings that are being offered by other agencies. This indeed is typical of the second reason for LTG's failure:—the unwillingness of voluntary agencies and governments to accept scientific evidence, where this points to the need for a change in accepted practice.

In view of this failure it became apparent that if scientists are to contribute to disaster research, there must be a re-assessment of the roles they play.

- First, acknowledging the limitations of the individual expert advisor, we should set out to develop multidisciplinary groups who can meld their individual talents into a new discipline of disaster research. UNESCO already has its earthquake team which visits the site of earthquakes for seismic research. There is no reason why analogous teams, independent of aid donors, should not be formed to investigate the social and medical impact of natural disasters. Research into the effectiveness of disaster aid could be immediately undertaken if only the aid agencies would agree to fund it. It would provide valuable evidence about any need for change in aid policies. In time, if such research became routine, results would be available to relief agencies to direct aid in any current disaster, rather than on a retrospective basis.

- Second, there is a need for longer term investment in research into the nature of disasters themselves. There is much we need to know about disasters, and the social response to them. Scientists as yet may have only an impersonal understanding of disasters, but at least they do know how to ask questions.

As always with research the problem is one of money, and investment in a programme of disaster research requires an act of faith by some funding agency. Justification for such faith may be found in the surprising yield of results from the fragmentary funding the subject has received in the UK and USA over the last 10 years—sufficient indeed to support two journals specialising in the field.

What can science achieve? Eloquent testimony exists in 'Maladie de Famine', a little known book of researches into the pathophysiology of famine which, although over 30 years old, is still the definitive work on the topic. It was a study conducted in the Warsaw Ghetto, by scientists, themselves victims of starvation and under sentence of death. No better memorial could be found to these men than to continue their work. □

*85 Marylebone High Street, London.

Science helps to rebuild Vietnam

Vietnam believes science to be the key to economic recovery. She hopes to have a "modern scientific capability" within 15 years. **Alastair Hay** reports

ONE of the longest wars in this century, the war in Vietnam, finally came to an end on 30 April 1975. It had claimed over a million lives and was fought for the best part of thirty years.

Few countries can have featured in as many television documentaries as Vietnam. For many of those watching, the image of Vietnam was fashioned by the television screen; it left a memory of a battered people and scarred countryside.

This is the legacy of war. Vietnam faces innumerable problems as she begins her programme of reconstruction. The problems in the health field illustrate the extent of the damage. The World Health Organisation cites figures from Vietnam of one million people infected by venereal disease, about 300,000 prostitutes, and half a million drug addicts, in a population of some 50 million. Endemic malaria affects some 18 million people in Vietnam. And the annual tuberculosis mortality rate is 30 per hundred thousand—the highest in the western Pacific.

Agricultural problems are just as daunting. Vietnam feeds 50 million people, but only farms 5 million hectares. Comparable figures for Eastern Europe cited by Vietnamese agriculturalists are estimated at a ratio of one person per hectare. If Vietnam is to become self-sufficient in food production—which is her intention—her tillage has to increase, and the efficiency of crop cultivation must improve.

But two obstacles impede her progress; unexploded weapons and bad weather. Literally hundreds of square miles of agricultural land have to lie fallow because of the presence of unexploded bombs and mines; mine-sweeping—currently being undertaken by the army—is required before the land can be pronounced safe.

The weather, too, has had disastrous consequences for the last two rice harvests. First it was too dry and then too cold. Yields have been too low to meet home demand and monthly rice rations have had to be reduced from 18 to 14 kilograms per person per month. To make up the remainder of the shortfall, scarce foreign currency had to be used to purchase rice on the international market. That currency was to have bought 3,000 tractors to aid the mechanisation of agriculture. In the event only 500 could be

Suffering from the ravages of war

acquired, all of which are in use in the Mekong Delta—the country's most fertile region. 500 tractors for a population of 50 million people can hardly be expected to revolutionise Vietnamese agriculture.

It is against this background that the scientists in Vietnam are having to orientate their work. They may lack the necessary material resources to tackle many of the problems confronting the country, but they have no lack of prestige. Science is seen by the Government as the key to Vietnam's economic recovery. Science and technology are important enough to warrant a spokesman in the Politburo—the highest policy making body. The minister with this responsibility is General Vo Nguyen Giap.

Giap is not well known in the scientific world. As his title might suggest, his has been a military career. Giap's claim to fame is as victor of Dien Bien Phu, the battle which in 1954 signalled an end to French involvement in Indochina. He has had a number of other responsibilities before assuming the portfolio of Minister of Defence, a post he still retains.

Vietnam's scientists were not displeased when Giap was nominated to deal with their problems. They find him an able minister and effective spokesman. To have one of the seven members of the Politburo—and a possible future prime minister—as their

representative is a situation any lobby would welcome.

Much of Vietnam's basic research is done in the Vietnamese Scientific Research Centre (VSRC) in Hanoi. The centre, now nearing completion, is part of the Soviet Union's aid programme to Vietnam. It will eventually house over 1,000 scientists, technologists and technicians in its four component institutes: those of biology, chemistry, physics and earth sciences. Two additional institutes (of oceanography and experimental biology) are located in the south of the country in Ho Chi Minh City (formerly Saigon).

Dr Nguyen Van Dao is the most senior of the seven vice-chairman of the VSRC; in effect he is its director. In an interview made easier with numerous cups of tea, many bananas and sweets he outlined his centre's research programme. The centre is, he says, "the main research institution in Vietnam". It also controls some Government programmes. One of the most important, says Dao, "is an investigation of our natural resources". Dao considers this knowledge to be vitally important for a developing country. The scientists in the centre will be surveying the coastal seabed as well as mapping land resources. Dao adds that many Vietnamese scientists

Alastair Hay was recently in Vietnam as a Nature travelling fellow. He was supported in part by the London Technical Group.

suspect that the United States could have valuable satellite pictures which would aid the surveys they propose to make. He acknowledges, however, that this information will probably be classified, but maintains that the Vietnamese would make better use of it than the Americans.

The VSRC, says Dao, is really only starting its research programme; its responsibility will increase in the future. Emphasis is currently placed on the problems of agriculture and medicine; on developing the country's electronics industry; and on establishing geophysics and hydrodynamics on a sound basis. "Our aim" says Dao "is to have a modern scientific capability in 15-20 years. This is a great responsibility. We are virtually starting from scratch after 30 years of war and at a time when the country is so short of resources". Dao would welcome extensive collaboration with Western scientists and scientific institutions. This, together with donations of scientific literature and equipment, could help Vietnam meet her twenty year programme. Dao expressed his appreciation for the aid the centre has received from other socialist countries, but adds that there is a desperate need for much more help.

On a tour of the centre it is apparent that some subjects are better provided for than others. Physics is generally acknowledged to be an expensive science, chemistry less so, but costly nevertheless. Historically this is how resources have been apportioned in Vietnam for both physicists and chemists were needed in the war effort. Biology and the other sciences all trailed behind.

The Head of the Institute of Biology, Dr Tuoc, has hopes that this situation is about to change in view of the Government's stated view that agriculture must be accorded more attention. Tuoc emphasises that the VSRC is concerned with basic science, but that this will have a practical application in the future. Some biologists in his Institute are engaged on plant breeding programmes with rice seeds obtained from the International Rice Research Institute in the Philippines; their aim is to produce a crop with a higher nitrogen content and to find a rice variety that will withstand a colder environment. Others are studying diseases of rice and tobacco—two of Vietnam's most important crops. Some of the research in vitamins in progress will include a compilation of these nutrients in the country's foodstuffs. Zoologists are similarly engaged on a programme of cataloguing Vietnam's fauna. The two rooms allocated to them in the Institute of Biology are filled with animal specimens destined eventually

Zoological specimens await attention

for a museum of natural history.

Of the four institutes in the VSRC, physics is by far the best equipped. The physicists have some real successes to their credit, and are perhaps the most confident of Vietnam's scientists. Professor Nguyen Van Hieu is a vice-chairman and in charge of the Institute of Physics. Open, warm and very forthcoming, Hieu is a perfect ambassador for Vietnamese science. Hieu is a high energy physicist and a professor at the Dubna high energy physics institute near Moscow. His institute has strong ties with Dubna and some Vietnamese physicists are currently engaged there on 1 to 3 year contracts. Many of the physicists—like most of the other scientists in the centre—are either trained in the Soviet Union or Eastern Europe; some studied in France and Germany.

The real achievement of Hieu's institute is the completion of a five-year programme to establish Vietnam's electronics industry. With many patents and raw materials bought from the West the physicists now produce their own transistors. It has proved to be an expensive undertaking, but well worth the financial support provided by the grants from industry. Vietnam's technologists have also worked on the electronics programme for its duration and in preparation for the transition of the work from pilot stage to full scale production. 1978 is destined to be the year of the first Vietnamese radio components.

To offset the cost of the transistors the physicists—in co-operation with the earth scientists—are actively studying the properties of Vietnam's natural resources. They hope to find the necessary raw materials to assist with

manufacture. In the past most of the research of the institute was of an applied nature; only recently has it been possible to do basic research. The six departments in the physics section cover a variety of topics. In theoretical physics, there are quantum field theorists, and solid-state theorists. In other departments some study semiconductor physics; some optics—for prism and lens manufacture to study the optical properties of semi-conductors and solid state materials—and quantum electronics; some work on technical physics for physical measurement; some on the physics of radiation; and some on crystallography.

The chemistry institute is headed by Dr Khoi Nguyen Huu. Vietnam's chemists are also engaged on a study of the country's natural resources. Their interest is centred on plant terpenes, steroids and alkaloids. In co-operation with botanists, plants used in traditional medicine are being grouped according to their chemical taxonomy. Eventually the active ingredients in the medicaments will be identified and synthesised. Certain stages of the process are feasible at the moment, but for positive fingerprinting all chemicals still have to be sent to foreign laboratories, a process the chemists find very time consuming.

The chemists are also studying the oil resources in Vietnam. The final aim of the programme is to assist industry to extract commercially important oils from anise, citronelle, cinammon, basilicum, dugenol and mint. With further departments for inorganic analysis in Hanoi, and others for oil chemistry and organic synthesis—mainly polymer chemistry—in Ho Chi Minh City the chemists have the necessary manpower for their work. Again the real problem is a chronic shortage of equipment and of available chemicals and solvents.

The VSRC is the best equipped of Vietnam's research institutions. Its programme is closely allied to the country's needs. But like all of Vietnam's research institutions it lacks many resources. Scientists, scientific institutions and governments in the West could do a great deal to assist the development of science in Vietnam. The aid which is currently given to Vietnamese scientists by Western donors is still far from adequate. Far more in the form of literature, equipment and exchange facilities for scientific co-operation is required.

When Vietnamese scientists are so obviously keen to make contact with their Western counterparts it surely is an opportunity to be grasped. A generous response from the West would be in order, for Vietnam's burden is one few would wish to carry. □

US establishes new directorate for applied research

In a renewed attempt to develop an effective mechanism linking scientific research to national priorities, the National Science Foundation (NSF) announced last week that it is to set up a directorate for applied science and research applications (ASRA).

The new directorate, with an initial annual budget of about \$60 million will replace the Research Applications Directorate, which has been responsible for the increasingly-criticised programme of Research Applied to National Needs (RANN) set up in 1971 in an attempt to bridge the gap between basic research and its applications.

The main difference between RANN and the new directorate is that whereas the former was primarily organised around individual problems, ASRA has been organised on more general principles.

Thus the RANN programme has at present five separate foci, the three most important being resources, environment, and the loosely-defined field of 'advanced productivity research and applications'. In contrast, ASRA will be divided into six functionally-defined units, including an office of problem analysis, a division of integrated basic research, a division of applied research, and a division of problem-focused research applications.

In addition, whereas RANN operated relatively independently of other research programmes financed by the NSF, ASRA will work closely with the foundation's three directorates for basic science: for example it will help to identify and subsequently stimulate basic research relevant to agreed goals.

In the US, the NSF was placed on this path by a 1969 amendment to its original act under which the foundation was authorised to "support, through other appropriate organisations, applied scientific research talent relevant to national problems involving the national interest".

In line with this amendment, and with President Richard Nixon's emphasis in a State of the Union message on harnessing the "discoveries of science in the service of man", the RANN programme was set up with responsibilities that included the identification of unrecognised research needs, and increasing the effective use of science and technology in dealing with national problems.

Despite stimulating a number of important research developments—for example into the use of geothermal and solar energy—the organisational basis

of RANN has in recent years encountered growing criticism, reflected in a gradual fall-off in its budget appropriation.

RANN faced the dilemma that if it defined research areas too narrowly, then many research proposals would not fit; but if the definitions were too broad, it was accused of encouraging a 'shotgun' approach to problem-solving without any clear description of research objectives.

Further criticism came from the scientific community, who objected to the apparent attempt to impose unreasonable goals on research efforts. In a highly critical report on RANN's research efforts in the applied social sciences, for example, the National Academy of Sciences claimed that these projects were "of highly variable quality and, in general, not impressive".

Although the Research Applications Directorate introduced a new structure for the RANN programme in 1976, unease remained, and in December that year a task force was set up under the chairmanship of Dr John Whinnery of the University of California, Berkeley, to 'review and advise the director on science applications across the Foundation'.

Dr Whinnery presented his report last summer, suggesting a number of alternative structures, from which the new directorate for applied science and research applications was selected by the NSF. The directorate, which comes into effect next month, is divided into six units as follows:

- The office of assistant director, which will carry out the policy-making, management, review and co-ordination functions of the directorate;
- The office of problem analysis, which will work with internal NSF and external groups and organisations in assessing problems for strategic and programmatic planning;
- The division of integrated basic research, a new section which will provide a direct link between ASRA and the basic research directorate of NSF by jointly identifying basic research related to significant national problems;
- The division of applied research, whose two sections—one dealing with applied social and behavioral sciences and the other with applied physical, mathematical and biological sciences—will support research proposals benefiting social, economic and technical problems and policy issues, as well as identifying and stimulating the growth of new technologies and processes

based on discoveries in various fields of science;

- The division of problem-focused research applications, which will support the application of scientific and technological capabilities to selected problems of society which are of critical national importance. (This division will initially contain four research programmes: earthquake hazard mitigation, chemical threats to man and the environment, biological alternatives for industrial feedstocks, and community water management); and

- The division of intergovernmental science and public technology, responsible for integrating science and technology into federal and state planning.

The head of the new directorate will be Dr Jack T. Sanderson, who took over the Research Applications Directorate last summer on the resignation of Dr Alfred J. Eggers, RANN's first director and now director of Lockheed's Palo Alto research laboratory.

Dr Sanderson claims that part of the new directorate has responsibility for "the most complicated part of the research spectrum" in contrast to the organisation of basic research, with its peer group system and its established paradigms. Linking research to national priorities is, he admits, an area in which the necessary mechanisms are "least well understood".

The stakes are high; no one doubts that there is a close relationship between basic research and technical development—but no one has yet come up with a totally convincing (and effective) way of pinpointing precisely how support for the former can stimulate the latter.

Will ASRA succeed where RANN seems to have failed? According to Dr Sanderson, the organisation of the new directorate is based on various models, each of which has already demonstrated a certain success, thus the integrated basic research division is modelled closely on the NSF's energy-related programme, instituted in response to the energy crisis of 1973. Under this programme NSF officials and research scientists together identified 40 priority research topics for which extra funding was subsequently made available. "Similarly the model for the problem-focused research applications division was developed after looking at the way applied research activities are carried out in government and private industry" Dr Sanderson says.

So far, the reaction to the new directorate from Capital Hill, from which some of the most vocal criticisms of

RANN were heard, has been a cautious welcome. But President Carter is known to be carrying out assessment of the effectiveness of the current organisation of research funding. A \$4 million programme providing basic support

for university research, known as "basic research stability grants", has already been "impounded" by the President from the NSF's 1978 budget prior to the outcome of this assessment. ASRA will therefore no doubt

receive close attention from both the House and the Senate during the hearings on the President's proposals for the science budget, due to take place in March.

David Dickson

Shcharanskii may soon be brought to trial —without a lawyer

THE US National Academy of Sciences has made an unprecedented demand for permission to send a legal observer to the forthcoming trial of Anatolii Shcharanskii, the Soviet cybernetician, who, until his arrest last March acted as spokesman for the unofficial 'Sunday Seminars' and was an active member of the Moscow Helsinki Monitoring Group.

Since his arrest, Shcharanskii has been held incommunicado, pending investigation on charges amounting to treason. The official 9-months investigation period expired in December, whereupon the investigating officers requested and were granted an extension of six months. Nevertheless, Shcharanskii's mother has now been told that she should find a lawyer for her son, not later than Friday, January 13, 1978—a somewhat ironic instruction since already at least 30 Moscow lawyers have refused to act in his defence.

According to a TASS statement of 22 December, the charge against Shcharanskii is that of giving assistance to a foreign State by systematically supplying his 'masters' with slanderous information about the Soviet Union, which was then actively used for ideological diversion against the Soviet Union, and supplying to the West information about Soviet enterprises and institutions, data which constituted official secrets. Already quasijudicial 'hearings' in Stockholm, New York, Paris and London, have presented a considerable bulk of evidence in rebuttal of these charges. While the publicity value of such moves may be considerable, the comment of *Literaturnaya Gazeta* that it is only a court which can determine Shcharanskii's innocence or guilt and that it is not for US lawyers to maintain law and order in the USSR does have a certain justification. The move of the NAS, in requesting the presence of an observer at the trial, is possibly proving more difficult to answer, since, although the hand-delivered letter was accepted by the Soviet Embassy in Washington, to date no answer has been received—a standard Soviet practice in dealing with embarrassing requests from abroad.

The NAS appeal was made by its

Anatolii Shcharanskii: held incommunicado

Committee on Human Rights, which was founded in 1976 at the requests of the grass-roots membership of the Academy. The Committee includes some 50 members of the Academy and in all, out of a membership of 1,200, over 350 members have done active work on behalf of dissident or imprisoned scientists. To date, their most notable success has been the release of the Argentinian Juan Carlos Gallardo, although they freely admit that the credit for this must go not to the NAS alone but to the whole human rights movement.

The Shcharanskii appeal noted the "widespread reaction . . . and grave concern" among Shcharanskii's colleagues in the USA and elsewhere, and suggested that further action against him would "severely damage scientific interactions with the USSR". This is not an idle threat—already the American Association of Computing Machinery has threatened to break off exchange relations with the Soviet Union over the Shcharanskii case. The Human Rights Committee of the NAS acts essentially as a mouthpiece of membership pressure. If there should be a widespread demand for a severance or suspension of such agreements

(and with more than a quarter of the membership actively involved in human rights activities, this is by no means impossible), the implications would be considerable. Although there exists a direct intergovernmental scientific exchange programme (established by the Nixon-Brezhnev talks of 1972), the exchange agreement between the Soviet and US Academies is a much older one (dating from 1959) and is both extensive and prestigious.

The NAS appeal is only one expression of the unprecedented concern which the Shcharanskii case has evoked. A number of factors are involved. One is, of course, the gravity of the charges. The choice of these charges, and suggestion of CIA involvement may in itself be a result of human rights action in the West. A few years ago, when intervention by such bodies as Amnesty International on behalf of dissidents became embarrassing, certain attempts were made to produce criminal charges so as to put the case outside Amnesty competence. Thus the refusenik physicist Viktor Pol'skii was accused of dangerous driving and manslaughter. The human rights activists promptly reformulated their terms of reference to include such cases, so that

from this point of view, the Shcharanskii case may be envisaged as the next move in a grim kind of human chess. Incidentally, the charge of disclosing state secrets is particularly ironic, since on graduation Shcharanskii carefully avoided taking a post where he might be exposed to classified information, which could hinder his chances of emigrating to Israel. Similarly, the Kiev physicist Vladimir Kislik, against whom, it is feared, similar charges may be in preparation is specifically accused of illegally sending abroad a scientific paper for publication. Not only is the information contained in it not secret; according to a western referee, the subject matter is so well known that he would not himself recommend publication.

Shcharanskii is somewhat of an exception among the refusniks, who, while awaiting their visas for Israel generally try to avoid dissident politics. The usual refusnik policy, as explained to *Nature* by Mark Azbel, former leader of the seminar is to avoid any confusion of the two issues, lest the

"Gee prof, there must be easier ways of getting in to observe the Shcharanskii trial"

would-be emigres be accused of subversion and the dissidents of Zionism. Whether such a distinction is possible is a moot point, since the Soviet authorities themselves seem bent on confusing it, by claiming, for example, that Sakharov is "really a Jew called Zuckermann". Shcharanskii, however, during his time in 'limbo' took an active interest in the Helsinki monitor-

ing group. Thus his arrest can be seen either as part of the renewed pressure on the Seminar, the 70 hard-core members of which are now being subjected to increasing surveillance including the use of cars with special listening devices, or as part of the campaign against the Helsinki monitoring groups two of which (in Ukraine and Armenia) had several members arrested over the (Western) Christmas holidays, when, it was presumably hoped, the news might pass unnoticed abroad.

From its very beginning, the Soviet human rights movement has been predominantly a movement of scientists, and this fact has undoubtedly contributed to an increasing concern about Western scientists with such problems. To date, except in the special case of psychiatry, where misuse of professional knowledge for political ends was involved, there has so far been no threat that protest abroad would lead to the severing of scientific relations. How far such sanctions will go in defence of Shcharanskii remains to be seen.

Vera Rich

Tory attacks energy gap forecasting—and the fast breeder

A BRITISH Conservative MP has attacked the hypothesis that there will be an 'energy gap' in the UK towards the end of this century, and questioned the economic sense of a commitment to a large programme of fast breeder reactors. The MP, Mr Nigel Forman, is the author of a Conservative Political Centre (CPC) pamphlet published this week titled *Towards a more conservative energy policy*. The document, while not a formal statement of Conservative Party policy, is according to a CPC spokesman "fairly close to the mainstream of Conservative thinking".

Mr Forman calls for emphasis on improving the efficiency of the production and distribution of energy, where 30% of primary energy is wasted, and proposes a flexible energy policy which operates on the demand as well as the supply of energy.

In a refreshing document which seems to verge on the radical rather than the conservative, the MP calls for more research on renewable resources, and for an approach to energy policy which will "liberate it from the requirements of the major vested interests". The conventional wisdom on renewable energy sources "seems to assume that they will make only a limited contribution to the energy supplies of the UK by the year 2000". However the main reason that the predictions are modest "is that until very recently

the R&D effort on nuclear energy, for example, exceeded that on all the renewable resources together by a factor of about 100".

Mr Forman brings his strongest criticism to bear on conventional energy forecasting and on the economics of the fast breeder programme. "It is when the experts begin to foretell the future that the trouble really begins" writes Forman. Undaunted by their predictions of an energy gap he argues that "what we are really being offered is little more than predictions of a change from a brief period of energy self-sufficiency in the 1980s and 1990s to a renewed period of energy import dependence—mainly for liquid hydrocarbons—at a time when the real price of energy is likely to be significantly higher than it is today. The threat, if there is one, is therefore to the prospect of continued exponential growth of final energy demand . . . it is not, nor need ever be, a threat to a society with improving rates of efficiency in fuel conversion and energy use".

An energy forecast is impossible, says Forman, without making prior political assumptions; and one of those assumptions ought to be that demand can be modified to meet supply.

On reprocessing and the proposed facility at Windscale, Mr Forman argues that "there simply will not be the necessary nuclear fuel throughput

from the Continent or elsewhere to justify such a large investment". Reprocessing, in other words, is uneconomic. The same is true of the fast breeder, says the MP, pointing out that the construction of around 20 breeder reactors of 1,300 MW each would cost a total of some £30 billion. "Simply to postulate such an enormous figure is to underline the foolishness of committing this nation to such a single-minded and excessive expenditure on a form of energy supply which we are unlikely to be able to afford and may not even need".

It may shock them, but with Prime Minister Jim Callaghan bearing down on Energy Minister Tony Benn to make him take a more pro-nuclear line it is beginning to appear that the best thing the Friends of the Earth could do would be to vote Tory.

Robert Walgate

Soviets look after their cosmonauts

THE purpose of the Soyuz-Salyut programme is not the carrying out of separate experiments, however unique. In a recent Tass statement, Flight Director Vadim Kravets announced that the ultimate aim is the establishment of a permanent scientific watch in orbit.

Accordingly, much is being done towards cosmonaut comfort and better working conditions, including the installation of a shower in Salyut 6 and the introduction of new semi-rigid space suits for extra-vehicular activity.

Since Salyut 4, the special computer-based Kaskad orientation system has been used to re-align the station as required by the programme of geo-physical, astro-physical, and solar observations, while the Delta autonomous navigation system has eliminated the exhausting and tedious work of orbital correction.

The possibility of natural disaster in orbit is considered minimal—pilot-cosmonaut Georgii Grechko has been quoted as saying that a direct hit by a meteor would be likely only once in two thousand years. Nevertheless, a Tass report of 24 December notes that a micrometeorite groove 1.5 mm deep has been observed on the glass surface of one of the Salyut 6 portholes. Grechko remains unruffled. □

First catch your bear . . .

AN unscheduled contribution to Soviet-US co-operation in the ecology of the Far North has been initiated by an Alaskan polar bear which, wearing a collar with a radio-transmitter attached, has set out across the Bering Strait to Siberia. When last observed, the bear appeared to be making for Wrangel Island, an area in which unfortunately, no major expedition is working at present. It has been agreed, however, that should the staff at the reserve base on Wrangel Island spot the bear, the collar and its transmitter will be returned to the Americans. □

\$17m for Salk institute

THE Salk Institute for Biological Studies is to set up a new "government services division" to carry out contract research for various government agencies.

This move has been made possible by the donation to the institute of the vaccine research and production facilities of a major pharmaceutical manufacturer, Richardson-Merrell, Inc. The value of the facilities has been assessed at \$17m.

The manufacturing portion of the facilities has already been sold. The institute will retain the research portion of the facilities, situated in Swiftwater, Pennsylvania, including 25 professional and technical personnel. □

MAN, with his increasing numbers and his wasteful use of resources, may damage both his immediate environment and the globe as a whole. Most of us wish to try to make the world a better place to live in, or at least to prevent further damage to its natural amenities. However, those concerned have different approaches to environmental problems, and it is perhaps worthwhile trying to decide which is the most effective.

Most publicity is given by the media to the extreme 'doomwatchers', who think that the only way to produce results is to frighten mankind into mending his ways. This was the technique of the Victorian hell-fire preacher. Today some environmentalists seem almost to exult in the prospect of impending disaster, as did the earlier preacher at the probability that his listeners would suffer the tortures of eternal damnation.

These extremists are unwilling to agree that there has ever been any improvement—they may even believe that this is the case. They are scornful of those with a different approach, and have their own vocabulary of insults. Those who express even the most qualified optimism are "complacent", and when this optimistic picture is supported by evidence that at least one type of damage had been controlled this is described as "simplistic". Even when it is impossible to deny that there has been some improvement they think up cryptic and subtle dangers from which we are suffering without being aware of their presence.

On the other hand we have those who take a more moderate line. They know that resources are limited, and they wish to make sure that these are used effectively. They wish to identify and quantify all dangers, so as not to waste their efforts on trivial and unimportant factors. As this group tends

Postponing doomsday

KENNETH MELLANBY

to lack glamour, it is seldom seen on television.

One organisation which has a reputation for moderation is the National Society for Clean Air (NSCA). I attended their annual conference at Harrogate recently. The members of this society are mostly recruited from the local authorities which are responsible for environmental protection, together with government and other scientists expert in different fields. The atmosphere at their conference was one of hope, not of doom. Most of the papers recorded growing improvements in the air quality of urban and industrial areas in Britain, and few spectacular dangers of any magnitude were reported.

The relative unimportance of the existing levels of substances like carbon monoxide and lead, which would be disastrous at higher concentrations, was discussed. However,

the conditions in areas with laggard local authorities, where smoke control was not enforced, were fully described, and those responsible were duly castigated. The members of NSCA had no doubt that their own efforts had contributed substantially to the real improvements which they reported. Some listeners complained that the Society was unduly complacent, and that it should be more militant even when existing pollution levels were apparently harmless and were, anyhow, decreasing, but these views received little support.

It will be clear that my sympathies are with NSCA. They get things done. Extremists will say that this is, at least in part, because doomwatch publicity has affected public opinion, and made it ready to respond to moderate views which might otherwise be ignored. I am doubtful. In the late nineteen sixties we were told that growing air pollution would make the major cities of Europe and America uninhabitable before the end of the century. Most and most people can recognise that things have got better and not worse. The Victorian preacher did not stamp out sin; many of his congregation did not really believe in the hell he promised them. The doom-besotted environmentalist is in an even worse position, for there is concrete evidence that his particular hell, if it exists, is getting further away as the moderates get on with the job of environmental improvement.

However, the world is still far from perfect. The extremists are not always wrong, and though their efforts at frightening the general public may be counterproductive, the experts would be wise to pay at least some attention to their views, for the cryptic dangers they stress have, at least in some few cases, been shown to be real.

In support of a boycott

SIR,—We read with great interest the letter by Richard Peto and Richard Doll (1 December, page 384) concerning the congress of the International Union Against Cancer which is scheduled to take place in Buenos Aires, Argentina October 1978 and the advisability of conducting a boycott in view of the violations of human rights in that country. It is stated that "advice and comments from other scientists, especially those who, unlike ourselves, have worked under repressive regimes, would be timely, both about the general advisability or inadvisability of such boycotts" in a country where there is conclusive evidence of widespread repression, torture and systematic violations of human rights.

The Association Solidarité Franco Argentine (a non-profit making, humanitarian organisation based in France) has contacted many Argentinian scientists regarding this problem. Although they asked not to be identified by name for fear of the consequences to their families still living in Argentina, the general opinion is that whatever measures are taken to show concern for the fate of the many scientists that have simply "disappeared" at the hands of the military government, there is one thing which should not be permitted: that the Argentinian government should use the success of the congress to claim to the world that the scientific community condones its present policies, by being present at the meeting and keeping silent about the plight of Argentinian scientists.

Unfortunately this is what seems to be happening in Argentina right now. A recent article from the strictly censored local press says that in spite of the efforts of some scientists, who pretend to be motivated for humanitarian reasons but in fact echo slogans of international terrorism, the congress will be a success. To prove this, the article mentions that only 500 participants had registered for the previous Florence meeting, compared to the 3,000 for the Buenos Aires event. Dr Humberto Veronessi, President of the International Union Against Cancer, is quoted as having said "I believe that to choose Buenos Aires for this meeting is one of the most

intelligent actions taken by the Union". This type of article suggests that the Argentinian generals have already invested high hopes in a "business as usual" congress as a measure of international acquiescence.

Among the many well known scientists to have publicly protested against the terrorising policies of the military Junta are Nobel prize winners Louis Néel, Alfred Kastler, Tsung Dao Lee and Hans Bethe (*New York Times*, 27 November, 1977). Concerned scientists attending the Buenos Aires meeting can take similar action by openly voicing their concern about the many Argentinian scientists who have vanished. This could be done by organising a petition to be read at the meeting or a press conference to be held in the presence of foreign journalists.

What has happened to Drs Federico Alvarez Rojas, Antonio Misetich, Gabriela Carabeli, Eduardo Pasquini, Julia Huarque, Federico Ludden, Manuel Tarchitsky and Juan Carlos Gallardo, all of them physicists, and the many others kidnapped, in many cases, with their families? Why aren't the numerous concentration camps open to Red Cross personnel? There is every reason to suspect that the worst is happening, just as it did in Nazi Germany, where similar questions puzzled many scientists, and massacres were taking place not far from the place where scientific meetings were being held.

Exiled Argentinian scientists beg the rest of the scientific community to stand up, whether by boycotts or in other ways. "Anti-science" sentiments will certainly not be aggravated by a public stance against torture and death. Many lives may instead be spared.

Yours faithfully,

GUY TASSART

Soft energy paths

SIR,—Peter Chapman is right to say (10 November, page 128) that my US calculations in *Soft Energy Paths: Toward a Durable Peace* should be redone for the UK—as several colleagues are now attempting. But in suggesting how my US numbers "fail on a num-

ber of technical issues" he may mislead UK readers unfamiliar with transatlantic differences.

First, he says my 0.55 capacity factor for US pressurised-water reactors (PWRs) is "unrealistically low", "absurd", and "silly", and so it must seem to people used to British gas-cooled reactors which are far more reliable (though allegedly more costly). Yet my citations show that the US empirical average through 1976 is 0.61 (0.59 for all light-water reactors) and falling as less reliable larger plants come on line; that the officially projected lifetime average is 0.57; and that the 10-year levelised average expected for new big PWRs on the basis of exhaustive statistical analysis of existing units is 0.49. Thus my assumed 0.55 is arguable either way but hardly out of court under US conditions. (European units tend to do better, Japanese ones worse.)

Second, in my analogy suggesting that if we could mass-produce power stations the way we do cars they would cost an order of magnitude less than they do, but we can't because they're too big, I did take account of generator cost and of equivalent engine lifetime. (I also noted many important economies of small scale—related to reliability, reserve margin, short lead times, etc—which are not "very dubious" nor even empirically controversial. For a taxonomy of scale issues, see my "Soft Energy Technologies" in the 1978 *Annual Review of Energy*.)

Third, the \$100/(m²+m³) solar installed price Dr Chapman quotes is for the mid-1980s (in 1976 dollars), not now; my late-1970s estimate of \$150 is broadly consistent with his. My ca 1985 price estimate is based on empirical prices now obtainable by careful shopping in a fairly mature solar market (such as California, with due adjustments for different climatic needs). Current UK prices in an infant market with little volume or diversity are understandably higher but do not indicate what could be achieved. I do not see why the "cost of storage in the UK" should be £300/m³ or even £40/m³, as I cited empirical installed US prices, for modular underground tanks of tongue-and-groove concrete slabs, equivalent to £12-20/m³ for sizes of order 10–10² m³, and several even cheaper methods are available. Perhaps they are

not in use in the UK, but that is not my fault. Further, solar heat's marginal-cost advantage is not fragile but robust: even with collectors costing twice Dr Chapman's assumed £50/m², neighbourhood-scale seasonal-storage solar space heating in the UK should compete with any long-run marginal source and probably with OPEC oil too (see the *Ann. Rev. En.* article).

Fourth, my analysis assumed neither large wind machines nor growing special biomass crops (rather, it assumed the conversion of present farm and forestry residues requiring no additional land); and I did not ignore, but repeatedly emphasised, the economic argument for matching energy quality to end-use needs. One of the reasons for persistent official commitments to a hard energy path is the prevalence of asymmetric cost comparisons: governments compare the costs of various types of big power stations and synthetic-fuel plants with each other, then compare the costs of soft technologies not with their hard-technology competitors but with the historically cheap fossil fuels that all are meant to replace. This makes some soft technologies fail a test which hard ones would fail by a far wider margin. So long as such chicanery goes unremarked, economically and politically disastrous energy policies will continue to prevail over common sense.

Yours faithfully,

AMORY B. LOVINS

*Friends of the Earth,
London, UK*

Gene inquiry is timely

SIR,—Your editorial (8 December, page 461) criticised the decision of the House of Commons Select Committee on Science and Technology to set up a subcommittee on genetic engineering. It did so in remarkably complacent terms which seem to us to pass all too lightly over the problems which remain unexamined and unresolved in this area and to exaggerate the extent to which public debate has occurred. In our view it is not true to say there has been exhaustive scrutiny or debate in the UK of the issues involved. The "general feeling" of scientists involved in the field may be that the hazards have been overplayed, but this attitude ignores other issues which concern the public.

Many of the hazards involved in genetic engineering require much wider examination. The analysis so far has been far from comprehensive, and the actions taken incomplete. For example, recommendations made by the Ashby Committee three years ago, such as the institution of epidemiological surveys

of workers in communities where these experiments are undertaken, have not yet been implemented. And the body established to regulate work in this field (the Genetic Manipulation Advisory Group) has few powers, relies on voluntary cooperation and is already experiencing problems in dealing with confidentiality of industrial information.

The examination of this area by the select committee could achieve much. It could help bring about a much wider appreciation of the far-reaching issues involved. It could also provide a valuable independent assessment of the policy-making procedures being created in this area which are currently screened from the public gaze by the protection of the Official Secrets Act. Now is the time for such an examination, before the problems of industrial exploitation are upon us. This is an urgent matter which requires as thorough an analysis as that at last being given to nuclear power.

We applaud the initiative taken by the select committee and feel sure that it will take the opportunity to take note of the wide range of views on this topic.

Yours faithfully,

BRIAN CUMMINS

What happened at Heimaey?

SIR,—In his search for a deontological code for volcanology, Haroun Tazieff (8 September, page 96) has elected not to practise his own preaching and indeed based some of his own arguments "on deliberately false data". We are astounded by his inclusion of the water-chilling of the Heimaey lava in 1973 in his tabulation of erroneous volcanological diagnoses, and his account of countermeasures taken by Icelanders as defence against lava flows on Heimaey indicate either lack of familiarity with relevant literature or wrong interpretation of actual facts.

In an attempt to prevent westward advance of the Heimaey lava over the town and towards the harbour, earth dams were bulldozed in late January and early February 1973. Experiments with chilling of lava-fronts by water-pumping started on 6 February and while lava advance could not be prevented, local slowing-down and diversion was achieved. Thus chilling of lava in this way is believed to have saved electric power-line installations for a while and diverted lava from the harbour wall on

6 March. Subsequently, pumps with total capacity of 1,000 litres per sec were employed, feeding a network of 20 cm diameter flexible plastic tubing system from the harbour to the lava fronts which were threatening further destruction of the town. This large-scale operation resulted in doubling of height of some lava fronts (Th. Einarsson, *The Heimaey Eruption*, Heimskringla, Reykjavik (1974)) as production of clinker and blocky rubble was increased on the lava surface. This increasing clinker accumulation rate seems to have decelerated or halted advance of the lava in certain areas.

Our knowledge of the mechanics of lava movement is still rudimentary. Recent theories, such as that of Hulme (*Geophys. Journ. Roy. Astr. Soc.* (1974)), make it clear that the strength of the flow front and channel levees are of great importance in controlling lava shape. As lava levees or flow fronts are made stronger and thicker, lava builds up behind these natural barriers. Lava will clearly attempt to break out or advance at the weakest front. By preferentially strengthening a levee or flow front by such a technique as water-cooling it seems probable that the lava will prefer to advance elsewhere. Levees or flow fronts are only minor parts of the total lava at any time, but increase in the strength of these areas may be highly effective in diverting lava. By choosing a strategic zone such as a levee, cooling need only be concentrated on a small part of the flow. Evidence from the Heimaey experiment suggests that the uncooled flow front ranged 10 m to 15 m in height, whereas the flow front treated by water pumping ranged from 20 m to 30 m and possibly as much as 40 m.

Finally there is a requirement to substantially improve our understanding of lava flow mechanisms. This is an area of research that illustrates the importance of volcanology turning from a qualitative to a quantitative science. In this way some of the noticeable subjectivity in judging volcanic phenomena, which is amply illustrated in Dr Tazieff's note, can be replaced by informed opinion, based on detailed understanding of the physics and chemistry of volcanic processes.

The determination of the people in Heimaey in fighting the advancing lava was not daunted by defeatist utterances of some sceptics at the time of the eruption. We hope that readers of the otherwise useful note by Haroun Tazieff will likewise dismiss his pessimism about the usefulness of water-cooling in diverting lava flows.

Yours faithfully,

Tangshan 1976: a case history in earthquake prediction

from Cinna Lomnitz and Larissa Lomnitz

Was the Tangshan earthquake of 1976, an event of Richter magnitude 7.8, predictable in the present state of earthquake forecasting in China? We shall attempt to show that it was not; in the absence of well-defined procedures of earthquake forecasting outside China our case rests on the detailed information obtained on two other large events, the Lungling and Yenyuen earthquakes, both accurately predicted by Chinese seismologists in 1976. A 10-day briefing in China has been of the greatest importance in making this report.

Chinese earthquake forecasting is a structured process of four stages: long-range, middle-range, short-range and immediate predictions. In the case of Tangshan a long-range prediction was issued in 1966, implicit in a directive of the Central Committee of the Communist Party, requesting seismologists to pay particular attention to North China and specifically to the Peking-Tientsin-Haicheng triangle. This directive was issued after the 1966 Hsingtai earthquake.

After the successful prediction of the Haicheng earthquake of 1975 it was generally expected that the long-term strains accumulated in the Peking-Tientsin area had been released (Fig. 1). This was a reasonable assumption because the region of North China is only moderately active. Yet there has been clustering of large events in time: for example, two shocks of magnitude 8 occurred in 1679 and 1695. No major earthquakes had previously been recorded in the immediate vicinity of Tangshan; the nearest events were a coastal shock ($M = 6$) in 1568, and an earthquake in Langcheng County ($M = 6\frac{1}{2}$) in 1624.

The earthquake occurred at 03:42:56 (Peking time) on 28 July, 1976. The location of the epicentre was 39.43°N 118.15°E , with a focal depth of 12 km. Twelve aftershocks exceeded mag-

nitude 6; the largest ($M = 7.1$) occurred on 28 July in Langcheng County—about 50 km to the northeast of the main shock.

Tangshan is in the centre of a rhomboidal area outlined by major crustal faults. The Tangshan fault proper is at least of Palaeozoic age; it is 40 km long, and runs along the top of a narrow uplifted block of Ordovician age. From geological and geophysical evidence it was concluded that the earthquake had been caused by a regional compressive stress from $\text{N } 86^{\circ}\text{E}$.

The main fault broke along an 8 km trace which went through the middle of the city of Tangshan. Right-lateral displacements of up to 1.58 m were observed. The vertical component of displacement of the east block was down towards the northern end of the fault break, and up towards the south. The trend of the fault trace was about $\text{N } 40^{\circ}\text{E}$; however, the fault trace of the main aftershock was nearly north-south. The displacement of this fault

was left-lateral. The aftershocks fell into two groups: the areal distribution and focal mechanisms for each group were consistent with each of the two fault traces. Hence the Tangshan earthquake may be described as a twin event.

The two earthquakes to be used as comparison were also twin events. The Lungling earthquakes (Southern Yunnan, 29 May, 1976; magnitudes 7.5 and 7.6) were successfully predicted; the immediate prediction was made by an amateur group at Lungling about 20 min before the first main shock. The Yenyuen earthquakes (Yunnan-Szechuan border, 7 November, 1976; magnitude 6.9, and 13 December, 1976; magnitude 6.8) were also predicted but the immediate forecasts were issued 3 days in advance. No lives were lost in any of these quakes.

Forerunners

At least 10 different kinds of phenomenon are monitored for purposes of earthquake prediction in China. They include observations of fault creep, regional and local tilt, gravity, shallow earth strains, direct current resistivity, groundwater fluctuations and changes in spring flow, telluric currents, geomagnetic observations, geochemical observations (particularly of radon in groundwater), changes in the velocity of seismic waves, changes in the distribution of small earthquakes in space, magnitude or time and observations of foreshocks. All these are quantitative forerunners. There are also a few qualitative forerunners, such as changes in animal behaviour and in the groundwater regime: these are termed 'macro-forerunners'.

The following forerunners were identified in connection with the Tangshan earthquake.

- Fault creep. Two stations located at 180 and 200 km from the epicentre, on the Babaashan Fault, recorded a 25-fold increase in the creep rate after May 1975. The fault became locked

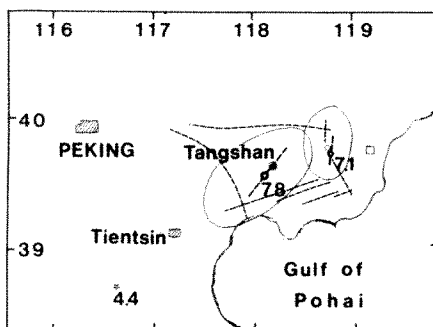

Fig. 1 Map of North China indicating the epicentre of the Tangshan earthquake (Peking magnitude = 7.8), and the second main event near Langcheng ($M = 7.1$). The ellipses represent the aftershock regions. The epicentre of the 'warning shock' near Tacheng ($M = 4.4$) is shown near the south edge of the map. Crustal faults outlining the 'Tangshan Quadrilateral' are indicated by broken lines; the two faults associated with the major events are represented by thick lines. The square symbol indicates Changli, a station which recorded a resistivity anomaly on 23 July, 1976.

between October 1975 and April 1976, then accelerated again to 33 times the average creep rate. About 20 days before the earthquake the direction of fault motion was suddenly reversed—unfortunately, at a time of heavy rainfall. (The effect of rainfall on the motion of the Babaashan Fault is not fully understood, but it is known to be a major effect).

● **Gravity.** Between July 1974 and July 1976 there was an increase of 100 μ gal in the Bouguer anomaly over the Tangshan quadrilateral. This was considered to be barely significant because the mean error was estimated at 40 μ gal.

● **Strain measurements.** Between May 1975 and July 1976 the quartz-rod strainmeter at Dahuidyan Observatory, across the Babaashan Fault (180 km from the epicentre), recorded a shortening of 0.3 mm, indicating regional compression. Piezoelectric strainmeters buried in pipes at depths of 3–10 m detected a sudden strain anomaly immediately before the earthquake. Dilatations and compressions were distributed in quadrant fashion about the epicentre.

● **Direct current resistivity.** Changli station, 80 km east of Tangshan, recorded a large decrease in resistivity beginning on 23 July. Between 30% to 40% of resistivity stations in North China showed some anomaly, but none was as clear as the one at Changli. The anomalies were widely scattered over distances of up to 300 km from the epicentre.

● **Fluctuations in wells.** Taking 23 July as a pivotal date, there was a marked increase in the reports of anomalies in wells. Only 59 such reports came in during the 5-day period preceding 23 July, but the number increased to 665 in the following 5 days.

● **Telluric currents.** Measurements of telluric current were not found to be particularly useful as the records were erratic. At Hsingchuang station, near Tientsin, a large telluric peak was recorded 13 min after the main shock, possibly due to some seismic coupling effect.

● **Geomagnetism.** No geomagnetic anomalies were mentioned at any time.

● **Radon.** Most Rd values had been increasing in North China since 1968. After February 1974 there were seemingly erratic fluctuations; after the Tangshan earthquake the Rd content has been dropping nearly everywhere. But there were no specific anomalies in the Tangshan area.

● **Small-scale seismicity.** There was no clear decrease in the minor seismicity after the 1975 Haicheng earthquake, as might have been expected if the regional strains had been released. A seismic gap had developed in the 'Tangshan quadrilateral' since about

Table 1 Short-range to immediate prediction

Time	Tangshan	Lungling	Yenyuen
<i>E</i> , 9 days	Resistivity drops at Changli Station	Increasing anomalies of Rd, magnetics, wells, hot springs, others	First foreshock, $M = 4.3$. Tsuli well dries up.
<i>E</i> , 3 days	Increase in well reports	Tsuli well dries up	Short-range forecast: E , 2 d, $M = 6-6.5$
<i>E</i> , 2 days			Second foreshock, $M = 4.0$. Tsuli well recovers
<i>E</i> , 1 day		Short-range forecast: E , 2 d, $M = 5-6$ Tsushun tilt base shows anomaly Large magnetic anomaly; animal behaviour; wells Foreshock, $M = 5.2$ More foreshocks Immediate forecast: Evacuation	Immediate forecast: Evacuation
<i>E</i> , 10 hour			Tzushun tilt base shows anomaly
<i>E</i> , 25 min			
<i>E</i> , 0	Earthquake		

1967; during 1975 this gap was outlined more clearly as only 14 shocks of magnitude 2.5 or greater occurred within the gap. The minor seismicity tended to migrate towards Tangshan: by 1976 many small shocks were occurring close to the edge of the gap.

Within the Tangshan quadrilateral the b -value decreased from 1.0 to about 0.35 between 1967 to 22 April, 1976. On this date an earthquake of magnitude 4.4 occurred in Tacheng (Hopei), near the southern edge of the gap. Afterwards the b -value recovered to about 0.6 just before the Tangshan earthquake.

The v_p/v_s anomaly about Tangshan followed a similar pattern. However, these anomalies were apparently detected after the earthquake, not before.

● **Foreshocks.** The seismographic record of the Tangshan station was recovered from the ruins: it showed only a few local shocks of magnitude less than 2 during the hours preceding the earthquake. This is conclusive evidence of the absence of foreshocks.

A comparative time history of forerunners of the Tangshan, Lungling and Yenyuen earthquake is shown in Fig. 2. At first sight no significant difference in the patterns emerges—up to the intermediate-range prediction. An intermediate-range prediction was indeed made for all three events. The magnitudes of all three earthquakes were underestimated. The differences appear at the short-range prediction stage. The comparative table above clarifies this point (E =time before the earthquake).

Notice that geophysical reversals (marked with an arrow in Fig. 2) were conspicuously absent before the Tangshan earthquake. The two exceptions (b -values and fault creep on the Babaashan Fault) were detected after

the earthquake, and neither could have been used to pinpoint the epicentral area. The Tacheng 'warning shock' of magnitude 4.4 occurred at a considerable distance from Tangshan. In contrast, foreshocks did occur both at Lungling and at Yenyuen, thus enabling local seismologists to close in on the epicentre weeks in advance of the earthquake. The onset of major foreshock activity, combined with sudden reversals of local tilt, magnetic field or fluctuations in ground water, will usually trigger an immediate prediction followed by evacuation.

A few words about the philosophy of earthquake prediction in China may be in order. The 1966 directive, usually attributed to Chou En-lai, outlined a five-point policy of earthquake prediction research: (1) give priority to prevention; (2) join the efforts of specialists and amateur workers; (3) combine indigenous and foreign methods; (4) work through the masses, (5) under the leadership of the Party. This policy has led to a distinctive scientific approach to seismological work. Initially many Chinese seismologists were reluctant to abandon deductive procedures based on the concatenation of hypotheses rigorously tested under controlled field situations. The key role of the masses was not recognised. Yet the observatories manned by specialists were too far-flung to be of practical use in detecting forerunners. Thousands of 'mass stations', built and operated by amateur observers, were needed to fill the large gaps between professional stations. Even those Chinese colleagues who remain moderately sceptical about earthquake forecasting methods now readily concede that the close collaboration between professional scientists and amateur observers represents a key element in achieving successful predictions.

Chinese seismologists do not claim any special knowledge concerning the cause and mechanism of earthquakes. After the successful prediction of the 1975 Haicheng earthquake, an official of the State Seismological Bureau bluntly warned: "There will be errors and disappointments, as well as unavoidable mistakes in reporting or failing to report individual forecasts . . . Earthquake prediction is a major complex scientific problem which overlaps many disciplines and which can hardly be expected to be solved at short notice . . . We have a long way to go. It will take time and much hard work". This note of caution, sounded 7 months before Tangshan, was by no means an accidental or isolated statement. Serious failures of prediction have occurred before the Tangshan disaster and will occur again. However, as long as the mechanism of earthquake generation is as imperfectly understood as it is today, the Chinese approach to prediction represents probably the most effective tool for controlling earthquake hazards in seismically active regions.

We are grateful to the State Seismological Bureau in Peking and to Chinese seismologists, for permission to reproduce the results of their investigations. Special thanks are due to Gao Wen-hsue of the State Seismological Bureau, Jin Hsue-shen and Li Yu-so of the Hopei Province Seismological Bureau, Ko Shen-min of the Institute of Geology, Ku Kung-hsu, Fu Cheng-yi, Sung Liang-yu, Chu Chun-zhen and

Fig. 2 Forerunners of the Tangshan, Lungling and Yen-yuen earthquakes, as referred to the time of the first main shock. A sawtooth pattern at the top indicates evacuation following an immediate prediction. Note that foreshocks serve to pinpoint an epicentral area, which is helpful in interpreting other anomalies. Intermediate prediction in all three cases occurred 15–150 days before the shock. Arrows, reversals; filled symbols, anomalies detected as significant.

Shi Jen-liang of the Institute of Geophysics, and Sung Chang-jiang, Chu Cheng-nan, Wang Feng-chi and Lin Tsun-yun of the Yunnan Province Seismological Bureau. □

Reabsorption of digestive enzymes: playing with poison

from Jared M. Diamond

In the course of digestion, the intestine and associated glands secrete quantities of solutes and water so large that the body could ill afford to lose such quantities in the faeces. Hence it is no surprise that distal parts of the intestine reabsorb most of these substances. Physiologists have studied in detail how, in a cycle termed the enterohepatic circulation, bile salts secreted by the liver are reabsorbed by the ileum and return by way of the bloodstream to the liver; and how salts and water secreted by salivary glands, stomach, liver, pancreas, and intestinal glands are reabsorbed between the duodenum and colon. Nevertheless, until recently there was no awareness of a cor-

responding circulation of the enzymes which the pancreas secretes into the intestine to split proteins, fats, and starches. Indeed, when evidence for such an enteropancreatic circulation was reported in 1975, it aroused 'interest but alarm' (on the part of Beynon and Kay, *Nature* 260, 78; 1976).

Reasons for the alarm were several. First, enteropancreatic circulation would require protein absorption by the intestine. While this has been demonstrated in some studies, much more attention has been paid to protein hydrolysis to dipeptides and amino acids in the gut lumen and subsequent absorption of the dipeptides and amino acids. Second, proteolytic enzymes and lipases might be expected to wreak havoc in the bloodstream, as illustrated

by their potency as the active ingredients of many venoms. Finally, there was no evidence for protein uptake from the bloodstream by pancreatic cells.

The missing evidence, and cause of the alarm, was provided by Rothman and colleagues (University of California Medical Center, San Francisco), who have added to the evidence (and to the alarm) in recent publications (*Science* 189, 472; 1975; *Nature* 257, 607; 1975; *Lancet*, 4 September, 494; 1976; *A. Rev. Physiol.* 39, 373; 1977; *Proc. natn. Acad. Sci. U.S.A.* 74, 4068; 1977). Their chain of evidence is as follows.

- Fifteen minutes after instillation into the gut of radioactive chymotrypsinogen, the inactive form of the proteolytic enzyme chymotrypsin, the radio-label appears in the pancreatic juice in a form comigrating electrophoretically with chymotrypsinogen.

- If pancreatic juice is diverted from entering the gut lumen and is instead drained off by a surgical fistula, protein secretion by the pancreas decreases 80–90%. Protein secretion is restored if pancreatic juice is returned to the gut or bloodstream. The calculated efficiency of enzyme recirculation, 80–90%, is comparable to that of the enterohepatic circulation of bile salts.

- The starch-splitting enzyme amylase is absorbed with its activity intact by a mechanism dependent on aerobic metabolism in the ileum. Absorption of a control high-molecular-weight substance, the physiologically inert polysaccharide inulin, is negligible under the same conditions. Similarly, Papp, Feher, Folly, and Horvath (Hungarian Academy of Sciences, Budapest) have reported duodenal absorption of pancreatic lipase intact (*Abstract, 1977 European Pancreatic Club Meeting*, 23).

- Radiolabelled chymotrypsinogen and amylase in the solution bathing or perfusing the isolated pancreas are taken up by the pancreatic cells and appear in pancreatic juice. The secretion rate of radiolabelled amylase in juice is increased by pancreozymin, the hormone that stimulates amylase secretion physiologically. That these phenomena are not due to breakdown and reincorporation of the radiolabel is shown by the negligible label in juice if the radiolabelled protein presented is albumin; by the absence of label in secreted amylase if the label presented is chymotrypsinogen; and by inhibition of labelled chymotrypsinogen secretion by an excess of unlabelled chymotrypsinogen, as expected for a saturable transport mechanism.

- There is a significant flux of amylase from pancreatic cells to an external bathing solution as well as into the pancreatic duct. Controls argue against

Jared M. Diamond is Professor of Physiology at the University of California Medical Center, Los Angeles.

this being attributable to a duct-to-bath shunt or cell damage. Thus, there is a two-way flux of amylase across the pancreatic cell membrane facing the bloodstream.

● Instillation of greater than normal quantities of pancreatic juice into the intestine of rabbits leads to 50% mortality—the only plausible toxic agents in pancreatic juice being the pancreatic enzymes themselves.

Mysteries remain. For efficient use of the enzymes in the gut, intestinal absorption should occur distally in the ileum as for bile salts, yet Papp *et al.* reported proximal (duodenal) absorption. Injection of proteases and lipases into a victim's bloodstream by poisonous snakes has spectacular consequences; why are the consequences of the postulated enteropancreatic circulation not equally spectacular? Are only the inactive forms of the enzymes absorbed by the intestine? If so, are the active forms lost in the faeces, and how can this be reconciled with 80–90% efficiency of recirculation? Does the intestine itself inactivate the enzymes while absorbing them? Both alarm and interest may be expected from physiologists until these questions are answered. □

Liposomes in biology and medicine

from G. Gregoriadis

A conference on Liposomes and their Uses in Biology and Medicine was held under the auspices of the NY Academy of Sciences on 14–16 September, 1977. It was chaired by D. Papahadjopoulos, Roswell Park Memorial Institute, Buffalo.

LIPOSOMES have been developed over the past 10 years or so both as model systems for the study of cell membranes and, as possible, vehicles for directing drugs to specific targets in the body. These two apparently unrelated aspects of the liposome were brought together at the conference.

The plethora of data on the physical properties of liposomes in their role as model membranes is now proving essential to the study of their interaction with cell membranes in their role as drug delivery vehicles. The opening lectures therefore—on the molecular organisation, lipid mobility, thermotropic and other properties of liposomes—were extremely relevant to their therapeutic applications. Fluidity

of liposomal membranes, for instance, which determines many of their structural and biological functions (interaction with cells for example) can be modulated by the incorporation of various molecules, by the hydrogenation of unsaturated phospholipid components (D. Chapman, University of London) or by Ca^{2+} which induces phase separation and subsequent fusion between liposomes (D. Papahadjopoulos, Roswell Park Memorial Institute, Buffalo).

Evidence of endocytosis as a mode of liposome–cell interaction was supplemented by alternative mechanisms such as fusion with mammalian cells (G. Poste, Roswell Park Memorial Institute), bacteria (M. J. Osborn, University of Connecticut Health Center) or viruses (A. M. Haywood, University of Rochester), as well as adsorption (R. E. Pagano, Carnegie Institution of Washington, Baltimore). However, such mechanisms, which relate to liposomal membrane fluidity and to cell or viral membrane components, may be less relevant *in vivo*. For instance, fusion has been seen in the absence of serum, components of which (α_2 -macroglobulin for example) adhering to liposomes could promote phagocytosis. Nonetheless, the possibility that mechanisms could be selectively induced to enable the access of liposomal drugs to a particular target organelle was raised by C. de Duve (International Institute of Cellular and Molecular Pathology, Brussels) who in this way introduced the conference to the exciting prospects of medical applications. These ranged from the treatment of tumours, enzyme and hormone deficiencies, metal storage diseases and arthritis to immunopotential and interferon induction.

Cancer chemotherapy, which perhaps unjustifiably dominated the meeting, covered conditions (such as lipid composition) under which liposomal drugs (for example, cytosine arabinoside (E. Mayhew, Roswell Park Memorial Institute; T. Kataoka, Japan Foundation of Cancer Research, Tokyo) or methotrexate, (H. K. Kimelberg, Albany Medical College)) given to ascites tumour-bearing mice prolonged survival more than did the free drugs. Although reduction of toxicity to normal tissues was a possible reason (Y. E. Rahman, Argonne National Laboratories) others, such as slow sustained formation of a more active metabolite (Ara-C triphosphate, Buffalo group) or sustained release of the drug itself were also thought likely. In connection with the possible treatment of lung metastases, markedly retarded removal of drugs from the lungs of animals given liposomal drugs by way of the airways was reported by R. L. Juliano (Hospital for Sick

Children, Toronto). Furthermore, localisation in animal tumours of a liposomal marker given intravenously was seen after scanning (B. E. Ryman, Charing Cross Hospital, London).

Ways to smuggle poliovirus into virus-resistant cells (R. Taber, Roswell Park Memorial Institute) and of enzymes into enzyme-deficient cells (G. Weissmann, New York University Medical Center) with the help of liposomes were of great interest and uptake of enzymes could be directed into specific cellular regions by appropriately designed liposomes. *In vivo* however, selectivity is much more difficult to achieve, especially in view of hepatic and splenic involvement. Some of the many properties of liposomes which influence their redirection to alternative sites as well as the role of the 'travelled' biological space (blood for example) were discussed (G. Gregoriadis, Clinical Research Centre, Harrow). Small liposomes could localise in target (tumour) areas more efficiently and liposomal lipid composition is essential in promoting the entrance of insulin given intragastrically into the periphery or in producing a better immune response to diphtheria toxoid. Homing of liposomes to specific cells, previously shown to occur *in vitro* by way of anti-target cell immunoglobulins incorporated into the liposomal surface, and successfully applied to the selective stimulation of lymphocytes (W. E. Magee, University of Texas, San Antonio) was, however, marred *in vivo* by the excessive participation of the liver.

In spite of their almost unlimited potential, liposomes have scarcely been investigated in man and the only therapeutic attempts have been enzyme replacement therapy of lysosomal storage diseases. An infant with glycolipidosis type II was given liposome-entrapped fungal amyloglucosidase but died before long-term observations could be made (Ryman). In a case of adult Gaucher's disease (glycosphingolipidosis) afflicting the reticuloendothelial system (liposomes home there spontaneously) the patient was repeatedly given liposomal human glucocerebrosidase: β -glucosidase over an 18-month period. There was marked relief of pressure and associated pain in the lower abdomen presumably as a result of a reduction in liver size. Each treatment was followed by pain in the liver which was proportional to the amount of enzyme used but which was absent with 'empty' liposomes (Gregoriadis). The ethics of the use of liposomes in such clinical trials before extensive animal experimentation were questioned. However, in view of the routine use of (Intralipid) phospholipid in intravenous feeding, selected phospholipids are likely to be less toxic

G. Gregoriadis is at the Clinical Research Centre, London.

than many of the cytotoxic drugs already in use, and it is rather the unknown way in which liposomes mediate drug action (or even toxicity) that one should consider. The implications are that under appropriate conditions, studies on marker-bearing liposome distribution in man could be a harmless and informative exercise, and that liposomal toxicity should always be examined in conjunction with the administered drug. Even so, in the absence of suitable animal models, the use of liposomal therapeutic agents in man might be acceptable. This is the case, for instance, with some human enzymes which in their free form have not been associated with toxicity and have not shown any beneficial effect.

The general feeling at the end of the conference was that although liposomes were already established as tools in the study of cell behaviour, their successful application in medicine was still a matter of speculation. On the other hand, as conventional drug treatment has in many instances proved unsuccessful, controlled drug delivery appears to be a hopeful alternative. In this respect, it is anticipated that liposomes will play a prominent part. □

A new human hepatitis virus

from Arie J. Zuckerman

THE identification of specific viral antigenic markers of hepatitis A (infectious or epidemic hepatitis) and hepatitis B (serum hepatitis) during the past few years has enabled sensitive laboratory tests to be developed. These, in turn, have led to a better understanding of the epidemiology, pathogenesis, immunology and nature of these infections; and, in the case of hepatitis B established the significance of this virus in severe chronic liver disease including at the very least a strong association with primary hepatocellular carcinoma in tropical and some subtropical regions. In addition, the specific diagnosis of hepatitis type A and hepatitis type B has revealed a previously unrecognised form of hepatitis which is clearly unrelated to either type. It is now the most common form of hepatitis occurring after blood transfusion in some

Arie J. Zuckerman is Professor of Microbiology and Director of the WHO Collaborating Centre for Reference and Research on Viral Hepatitis at the London School of Hygiene and Tropical Medicine.

Polymer diffusion disentangled

from P. D. Calvert

IN 1971 de Gennes predicted that the diffusion coefficient of a polymer chain in a gel would be proportional to the inverse square of the molecular weight (M) and with some reservations extended this prediction to self diffusion of molten polymers (*J. Chem. Phys.* **55**, 572; 1972). At the time the only available data, from NMR measurements by McCall *et al.* (*J. Chem. Phys.* **30**, 771; 1959), gave an exponent of $-5/3$. In this issue of *Nature* (page 143) Klein presents data for the self diffusion of polyethylene which confirms de Gennes prediction.

Self diffusion is not really an important property of polymers and most diffusion measurements are for gases or other small molecules; previous work of Klein and Briscoe and others in this field was described in a recent *News and Views* (**269**, 290; 1977). Viscosity is, on the other hand, an important property since most plastics are formed by squirting liquid polymer through small holes. Both self diffusion and viscosity involve molecules moving relative to one another, so one usually expects the diffusion coefficient to be inversely proportional to the viscosity.

Diffusion and viscosity in dilute polymer solutions has been well explained using Rouse models, where the polymer chains are viewed as strings of beads joined by springs and acted on by the flowing solvent. Molten short chain polymers can be treated similarly and one expects and gets a viscosity which increases proportionally to molecular weight, that is to chain length. At a critical molecular weight characteristic of each polymer this tidy state of affairs stops, and melt viscosity starts increasing proportionally to molecular weight to the power of 3.4. The reason for this is that the chains become entangled and difficult to separate. Exactly how this works and why the exponent is 3.4 has never been properly explained, though people have managed to obtain the right answer by rather

unconvincing routes.

De Gennes approached this problem by considering a chain molecule moving through a cross-linked network, so that the moving chain must wriggle through the network in a snake-like fashion. De Gennes christened this motion reptation. In essence the network chains can be thought of as forming an elastic tube within which the free molecule is constrained to move. This idea can be extended to molten polymers if we allow that the tube itself can move and reform, so that chain motion will be a combination of motion within the tube and motion of the tube. Reptation, motion within the tube, gives diffusion dependent on M^{-2} and viscosity on M^3 (de Gennes *Macromolecules* **9**, 594; 1976). Motion of the whole tube was tackled by Edwards and Grant (*J. Phys.* **A-6**, 1169, 1186; 1973) who showed that this gave a diffusion dependence of M^{-3} and viscosity of M^3 , and thought that this motion would dominate in molten polymers. What we conclude from Klein's results is that the tubes do not seem to move and reptation dominates, at least in diffusion. However, this still leaves us with the mysterious $M^{3.4}$ dependence observed for viscosity.

The idea of entanglements arose when workers on rubber elasticity found that cross-linked polymers acted as if they contained more junction points than are actually put in. It is a convenient concept, but carries with it the notion that a few interactions between chains act as tie points which are important for their properties, whilst the vast mass of interactions have little effect. It seems that reptation may lead to entanglements becoming redundant. Their replacement with a more realistic description of friction between random chains would be a real improvement.

areas of the world (*Report of the WHO Expert Committee on Viral Hepatitis*. Techn. Rep. Series, No. 602, 1977). Although there are as yet no specific laboratory tests for identifying this new form of hepatitis, recent studies nevertheless stress the importance of this infection.

Results obtained from several recent surveys of post-transfusion hepatitis in

the United States provide strong epidemiological evidence of 'guilt by association' of an infection of the liver referred to in the USA as non-A: non-B hepatitis. Perhaps the most convincing report has just been published by Hoofnagle and colleagues (*Ann. intern. Med.* **87**, 14; 1977) after retesting serum samples that had been frozen from transmission studies con-

ducted in volunteer male prisoners in the USA in 1951-54 as part of a study on means of inactivating hepatitis virus in blood. The viral aetiology of hepatitis was in fact established by successful transmission experiments to volunteers first in Germany in 1942, in Palestine in 1943 and later by more extensive studies carried out in Britain and in the United States. Because a wide range of laboratory and other animals including monkeys, pigs, gerbils, jerboas, desert rodents and others had been inoculated with negative results permission for human inoculation tests was sought and obtained (*History of the Second World War. United Kingdom Medical Series. Medicine and Pathology*, 252 (Eds MacNalty, A. S. & Zachary Cope, V.) HMSO, 1952). In the series of volunteer studies carried out in the USA in the early 1950s, serum samples from six blood donors, implicated in the transmission of post-transfusion hepatitis after a single unit transfusion, were each inoculated into groups of 10-20 male prisoners. Sera from five of the implicated donors induced hepatitis in recipients. The serum samples collected during these studies have now been tested by Hoofnagle *et al.* for evidence of infection with hepatitis virus type A and B, cytomegalovirus and EB virus. Two of the donor sera contained markers of hepatitis B virus and transmitted hepatitis B infection to all susceptible recipients, two of

whom developed hepatic coma. The sera from the remaining three donors did not contain hepatitis B markers, but these sera were nevertheless infectious. A form of hepatitis was transmitted to nine volunteer recipients which could not be attributed to hepatitis A, hepatitis B nor to infection with cytomegalovirus or EB virus. The incubation period ranged from 18-89 d and the clinical illness was similar in most respects to hepatitis B. Of added significance was the finding of some evidence of persistent liver damage in one out of ten recipients who developed hepatitis type B and in two out of six volunteers who developed the unspecified type of hepatitis (non-A: non-B hepatitis).

In a recently completed survey on the efficacy of immunoglobulin (gamma globulin) for the prevention of post-transfusion hepatitis, Knodell and colleagues (*Gastroenterology* **72**, 902; 1977) identified 44 patients with acute non-A: non-B hepatitis. Sixteen of the patients had persistent biochemical evidence of liver damage 6 months after the acute illness. In 10 patients the abnormality of liver enzymes continued for 1-3 years and liver biopsy in each patient revealed histological evidence of chronic liver damage. It was further observed that 9 out of 22 patients who developed evidence of chronic hepatitis received albumin solution as a placebo, whereas only 1 of 11 patients who were given

normal immunoglobulin developed chronic hepatitis and none of 11 patients who received hepatitis B immunoglobulin. Further evidence for the existence of a third type of human viral hepatitis is provided by Dienstag and colleagues (*Ann. intern. Med.* **87**, 1; 1977) who investigated the cause of acute hepatitis in 45 patients admitted to a hospital in Los Angeles. There was no laboratory evidence of infection with hepatitis A, hepatitis B, cytomegalovirus or EB virus in 20 patients. It was noted that in nearly half of these patients infection followed the type of exposure traditionally associated with hepatitis B such as blood transfusion, plasmapheresis and occupational contact with patients.

These reports suggest the following: first, a carrier state of this newly recognised hepatitis agent since the infection is transmissible by blood transfusion (and probably by other routes) from apparently healthy donors; second, the infection must be common since pooled immunoglobulin seems to contain antibody as shown by the prophylactic efficacy of immunoglobulin in one study, and finally it seems that this infection may progress to chronic liver disease. The aetiological spectrum of viral hepatitis in man has thus been dramatically widened and there is an urgent need to develop specific laboratory tests for identifying this previously unrecognised virus or viruses. □

Great and Lesser Ararat from the North-east

So impressive a mountain, so long associated with man's faith and history, would have been appropriately placed among the most ancient landscapes of the earth's surface. Some scenes suggest only the changes of yesterday; others set us thinking of the earliest condition of our world. We naturally look for a kind of consonance between the venerable antiquity of the associations

which gather round Ararat and the primeval character of the finds, on closer research, that while most of these ridges have received their latest upheavals at a recent geological date, they yet for the greater part belong originally to earlier periods of disturbance, some of them, indeed, bearing witness to many successive uplifts during a vast section of geological time.

Yet further examination will bring before him evidence that along some of these lines of earth-folding, volcanic action has of old been abundant; and that the present Mediterranean volcanoes are but the lingering remnants of the chain of actively burning mountains which ran through Asia Minor and crowned the peaks of the Caucasus. And he will discover that just as there have been successive uplifts of the same axis or mountain-chain, so have there been widely-separated outbursts of volcanic activity during a long course of ages from the same focus of discharge.

In the middle distance is shown the alluvial plain of the Araxes. Below the snowy cone and icy cliffs of the Greater Ararat a deep cleft or recess appears with huge cliffs somewhat like the Val del Bove of Etna, and no doubt due to some of the volcanic explosions of the mountain. On the sky-line of this slope, towards the base of the larger cone, some of the late cinder-cones and craters appear. Some of these are still so fresh and perfect that they look as if they had been active only the other day and might blaze forth again tomorrow. The graceful outline of the Lesser Ararat rises on the left.

review article

Chromatin

Gary Felsenfeld*

The approximate shape of the chromatin subunit called the nucleosome is now known, but its internal architecture is not well understood. Recent studies reveal details of the organisation of DNA within the nucleosome, and show that the arginine-rich histones are essential to DNA folding. Nucleosomes or structures related to them seem to be present at points of DNA replication and transcription; interactions within and between nucleosomes are likely to play a critical part in these processes.

RECENT studies of chromatin structure have focused on the nucleoprotein subunit called the nucleosome¹⁻⁹. Starting with this one certain structural element, investigators have worked in two directions, either examining the internal structure of the nucleosome, or speculating on ways of assembling arrays of nucleosomes to give the higher orders of structure and DNA compaction that are characteristic of chromatin in the nucleus.

The canonical nucleosome consists of a well defined length of DNA^{7,8} (about 200 base pairs) complexed with an octamer³ of histones. The octamer contains two copies each of the slightly lysine-rich histones H2A and H2B, and the arginine-rich histones H3 and H4; H1 is not part of the nucleosome, but is associated with it. As new data have accumulated, these general features of the nucleosome model have been confirmed, but the details have, not unexpectedly, been modified. For example, it is now clear that the amount of DNA per histone octamer can vary between about 140 and 240 base pairs, depending upon the organism and tissue from which the nucleosomes are isolated¹⁰⁻¹⁶; even within a single cell type, the spacing is not homogeneous^{15,17-19}. The evidence for this variability comes from studies in which nuclei are digested briefly with staphylococcal nuclease. The first points of attack are within the sensitive DNA 'spacer' or 'linker' regions separating the repeating units. This limited digestion releases nucleosome oligomers and monomers that are close to full-sized, and extrapolation to zero digestion time gives the size of the fundamental repeat. It is the repeat measured in this way that is found to vary with the source of the nuclei. Further digestion results in rapid preferential degradation of spacer DNA, leading, in the case of the monomer, to formation of a relatively stable nucleosome 'core' containing the histone octamer and a DNA segment 140 base pairs in length²⁰⁻²². The size of this segment is invariant in all chromatin samples so far examined^{10,12,15}. The variability of the length of DNA in the nucleosome repeat thus derives entirely from variation in the length of the spacer regions that separate the cores.

The earliest physical studies of nucleosome core structure suggested a particle roughly spherical in shape, about 100 Å in diameter. There was also a proposal, however, that the nucleosome was disk-shaped²³. Neutron scattering studies, which measured the contribution of the DNA to the radius of gyration of the particle, unambiguously placed the DNA at the exterior of the nucleosome^{6,24,25}. Recently, detailed study of the neutron and X-ray scattering behaviour of nucleosomes in solution has

led investigators at Searle²⁶⁻²⁸ to conclude that the nucleosome could not be spherical. Their data were fitted best by a flattened cylindrical structure about 100 Å in diameter and 50 Å in height, with the DNA wrapped around it to form a pair of rings at the top and bottom.

Though solution scattering studies can eliminate possible models of the core shape, they cannot be used to prove them unambiguously. Fortunately, more direct information about nucleosome core shape has now been provided by the work of Finch, Klug, and their collaborators²⁹, who have crystallised nucleosome core preparations and carried out combined X-ray diffraction and electron microscopic measurements with a resolution of 20 to 25 Å. Some caution is necessary in comparing their results with those from neutron scattering, since the crystallised core particles contained histones that had undergone partial proteolysis. However, there is reason to think that this results in only minor changes in structure. The crystallographic data show that the nucleosome core is a flat disk about 110 Å in diameter and 57 Å in height, in excellent agreement with the neutron scattering model. Given the present resolution, the exact path of the DNA cannot be determined, though the electron density map is not inconsistent with the location of DNA on the periphery of the particle, as demonstrated earlier by neutron scattering. If it is assumed that the 140 base pairs of DNA form a uniform superhelix wrapped around the cylinder, the superhelix must have a diameter of about 90 Å and a pitch of about 28 Å, corresponding to between 75 and 82 base pairs per superhelical turn of B-form DNA.

Action of nucleases on the nucleosome core

Additional inferences²⁹ about the structure can be made by combining information from diffraction with data obtained from nuclease digestion studies. It has been known for some time that the DNA of the nucleosome is susceptible to internal cleavage by nucleases. Although the spacer DNA is the preferred target, the nucleosome core is also attacked, at a slower rate^{30,31}. Staphylococcal nuclease cuts across both of the DNA strands³⁰, whereas other enzymes, such as pancreatic DNase, usually make single-strand cuts, so that the cutting pattern is somewhat obscured unless the digestion product is denatured³¹. Although the details of the process differ, all of the enzymes produce an array of fragments of discrete size. The pattern of single-strand cuts generated by pancreatic DNase is especially striking: when DNA from a partial digest of nuclei is denatured and subjected to gel electrophoresis, a series of discrete bands is observed, corresponding to DNA sizes that are integral multiples of ten nucleotides³¹ (Fig. 1, left). It is evident that there are discrete cleavage sites within the nucleosome; the way in which

Fig. 1 The products of internal cleavage of nucleosomal DNA. Duck erythrocyte nuclei were digested with nuclease and the DNA purified, denatured, and electrophoresed on a polyacrylamide gel. Left channel: Pancreatic DNase (DNaseI) digest, 23% of the nuclear DNA acid soluble (after ref. 31). Right channel: Spleen acid DNase (DNaseII) digest, 60% acid soluble. Migration is from top to bottom. The dark-stained bands correspond to single strand DNA fractions separated by 10 nucleotide intervals in the approximate range 140–30 nucleotides. (From ref. 60.)

band intensities vary shows that the sites are not equally accessible.

The electrophoretic pattern is a map of the relative frequency of a given separation between sites, but it tells us nothing about their absolute location. For that, the nuclease digestion experiment is repeated starting with nucleosome core particles that have been labelled *in vitro* with ^{32}P at the 5' termini of the DNA chains. The electrophoretic pattern of radioactively labelled fragments reflects the distance of susceptible sites from a fixed point on each chain. This experiment has been carried out independently in three laboratories with roughly comparable results^{32–34}; there is general agreement that the sites 30, 80, and 110 nucleotides from each 5' terminus are quite insensitive to attack by pancreatic DNase. The absence of any fragments of these sizes means that each chain of the duplex is resistant to attack at these distances from its 5' terminus. This suggests a symmetrical distribution of protein–DNA contacts as a function of distance from the 5' termini of the antiparallel strands^{32,33}.

Such a symmetrical distribution of cleavage sites would be expected in a structure containing a dyad axis, as has been proposed on the basis of histone interaction studies³⁵. The possibility of this two-fold symmetry in the histone octamer itself has led to the proposal that the nucleosome not only contains a dyad axis, but is capable of unfolding into two symmetrical half-nucleosomes, perhaps as part of some mechanism of replication or transcription³⁶. A dissociation pathway of this kind is suggested by studies of histone interactions in the absence of DNA. When nucleosomes are dissolved in 2 M NaCl, the liberated core histones (H2A, H2B, H3, and H4) have been reported to form 'heterotypic tetramers' containing one molecule of each histone species³⁷. However, there is an unresolved disagreement about this observation,

since other workers report that the predominant species in 2 M NaCl is an octamer, rather than a tetramer³⁸.

Regardless of the nature of these histone interactions, the idea of nucleosome unfolding is supported by a number of studies of the effects of ionic strength and denaturing solvents on the nucleosome's physicochemical properties^{39–42}. Furthermore, it has recently been reported that at low ionic strength, the nucleosome as seen in the electron microscope appears to split into a pair of smaller particles⁴³. For example, the normal SV40 minichromosome, which bears 20–24 nucleosomes⁴⁴, is converted into a structure with a slightly greater contour length, but with 40 to 50 beads, each about 3/4 the diameter of the normal nucleosome.

Further evidence for a bipartite nucleosome structure comes from studies of the action of spleen acid DNase, a DNaseII, on chromatin. This enzyme can act on nuclear DNA to generate fragments that are multiples of 100 base pairs in length, suggesting that in addition to preferred cleavage sites between nucleosome cores, there may be another in the middle of each core. Although no corresponding nucleoprotein particle has been isolated, the results are consistent with the presence of a site of symmetry within the nucleosome. Preferential cleavage at this site is not seen in isolated nucleosomes, and only occurs in certain ionic conditions in nucleosome oligomers or purified chromatin; the inference can be made that nucleosome interaction and higher order structure are connected with this phenomenon.

Although the existence of a dyad axis in the nucleosome is not proven, it is certainly reasonable to introduce this symmetry element into any tentative model, and Finch *et al.*²⁹ have done so (Fig. 2). In addition, they have made use of the nuclease digestion studies mentioned earlier^{29,33}, which show that most sensitive sites, measured from a labelled 5' terminus, occur in pairs separated by 80 nucleotides along a given chain. Such a pattern could be explained if each superhelical turn contained exactly 80 base pairs, so that the backbone elements of adjacent turns were closest to one another when separated by 80 base pairs along the double helix. Since in this model the adjacent turns are separated by only 28 Å along the nucleosome surface, it is argued that the local environment, and hence nuclease sensitivity, would be the same for two elements separated by the length of a supercoil turn (Fig. 2).

This analysis is an attempt to explain the modulation of site accessibility, but avoids the more difficult question: what is the origin of the restriction that confines nuclease site separation to multiples of ten nucleotides? Two kinds of explanation have been proposed; both are related to the 10 base pair helical pitch of B-form DNA fibres, and both postulate that this periodicity exists in nucleosomal DNA. In the 'kinky helix' models^{16,47}, linear segments of B-form DNA are discontinuously bent at intervals of ten base pairs; the nuclease-sensitive sites are at the bends. A second model for DNA folding involves continuous bending of the DNA in such a way that the double

Fig. 2 Proposed superhelical path of DNA wound around the nucleosome core, showing nuclease cleavage sites and proposed dyad axis. (From ref. 29.)

helix makes one complete turn, relative to the nucleosome surface, for each ten base pairs. If a strand is accessible to nuclease only when it protrudes most from the nucleosome surface, nuclease-sensitive sites will occur once every ten nucleotides on each strand³¹. If cleavage occurred precisely at these sites, cuts on opposite strands would be separated by six or four nucleotides in a staggered arrangement. On the other hand, cuts occurring at kinks would be found either directly across from one another, or separated to give a stagger of ten nucleotides. These predictions can be tested directly by isolating double-stranded DNA from pancreatic DNase (DNaseI) digests. Wherever cuts on opposite strands are close together, fragments separate from each other, forming a series of small double-stranded molecules with single-stranded tails. The size of these tails, and thus the size of the stagger, can be determined by repairing the single-stranded region with a DNA polymerase, which extends all chains having recessed 3'-OH termini. It is found in this way that the cutting pattern corresponds to a stagger of 8 nucleotides (3'-OH recessed) and 2 nucleotides (5'-P recessed) between adjacent cutting sites on opposite strands^{18,19}.

This result is consistent with neither of the predictions described above. It can be made consistent with either by assuming that the site on the nucleosome recognized by the enzyme does not coincide with the cutting site, but is appropriately displaced in the 3' or 5' direction (Fig. 3). Further support for this idea comes from similar studies⁵⁰ of the mode of action of spleen acid DNase, a DNaseII. The nucleosome digest pattern of this enzyme is like that of DNaseI (Fig. 1), but detailed examination shows that in this case the cutting sites are staggered by six and four nucleotides (Fig. 3). Making use once again of labelling at the 5' terminus, the relative positions of the DNaseI and DNaseII cuts can be compared. It is found that the two sets of cutting sites are related to each other by a common dyad axis. Using somewhat different procedures, staphylococcal nuclease can be shown to cut at still another set of sites, which share the same dyad axis⁵⁰. It seems that the common recognition site is determined by the nucleosome structure, but the exact cutting point depends upon the enzyme.

Nucleosome folding and DNA supercoiling

Unfortunately none of this enables us to decide between kinked and continuously deformed models of DNA in the nucleosome. It is certainly possible to construct acceptable models of superhelical DNA by continuous deformation of the double helix^{29,51}. Estimates can be made of the energy required to bend DNA into a continuous supercoil with the dimensions of a nucleosome, using a well known relationship between the persistence length of such a stiff coil and its average bending force constant⁵². According to this model, about 20–28 kcal/mol of nucleosome are required to bend the DNA. The electrostatic forces which bind histones to DNA are very large at physiological ionic strength. The integrity of the folded nucleosome may therefore depend upon the attractive forces between histones within the nucleosome; if they are weak, the nucleosome will unfold. The free energy of interaction of histones in the nucleosome can be estimated, starting with free energy values measured in solution^{35,53}. It is found⁵² that one or two pairwise interactions of average strength would be sufficient to maintain the nucleosome in closed form. An unfolding pathway, such as that leading to half-nucleosomes, might involve disruption of just such a small number of interactions, and permit a delicate balance between folded and unfolded forms. It should be noted, however, that such an unfolding may not be an obligatory pathway for nucleosome assembly or disassembly: a particle with most of the physical properties of a nucleosome can be generated⁵⁴ by combining a DNA fragment 140 base pairs long with a histone octamer in which the proteins have been crosslinked, preventing histone dissociation and presumably interfering with unfolding as well.

Whether the DNA of the nucleosome is kinked or continuously deformed, every proposed structure must not only have

dimensions appropriate to the nucleosome, but must also satisfy the topological criteria implicit in experiments⁵⁵ which demonstrate the ability of the core histones to induce supercoiling. These experiments show that each octamer of core histones induces supercoiling in closed circular DNA equivalent to a change in linking number (ΔLk) of about -1 , reflecting additive contributions from changes in both the writhing number and the twist of the DNA^{56,57}. The simple models of kinking or continuous deformation described above fix the final state of twist of the DNA; similarly, the writhing number can be calculated for the proposed superhelical path of the double helix along the surface of the nucleosome²⁹. Thus, ΔLk can be calculated for the conversion of relaxed to nucleosomal DNA.

Fig. 3 Relative locations of the cleavage sites on nucleosomal DNA of pancreatic DNase (I), spleen acid DNase (II) and staphylococcal nuclease (S). The dot represents the local dyad axis of the cuts. (From ref. 50.)

If the fully relaxed conformation has ten base pairs per turn, as is generally assumed for B-form DNA, the agreement between the calculated and observed values of ΔLk is not good. It has been suggested²⁹, on the basis of recent theoretical calculations of DNA conformation, that B-form DNA in solution (though not in fibres) may in fact have about 10.7 base pairs per turn. This would certainly remove the discrepancy in ΔLk by changing the starting value of the twist, leaving the nucleosome model unchanged. At this point, none of the experimental observations concerning nucleosome structure, DNA supercoiling, or DNA conformation in solution is sufficiently precise or incontrovertible to permit a decision as to which is in error.

Role of arginine-rich histones

Nucleosomes can be reassembled by mixing DNA and histones under controlled conditions. The reconstituted particles have the characteristic beaded appearance in the electron microscope⁵⁵, and give typical subnucleosome fragment patterns when digested with nucleases^{30,58}. Recently, the four core histones have been reconstituted with DNA 140 base pairs in length, to give a homogeneous preparation of particles with sedimentation coefficient identical to that of native nucleosome cores⁵⁹.

The availability of reliable reconstitution methods makes it possible to examine the role of each histone component in the organisation of the nucleosome, by systematically omitting one or more from the reconstitution procedure. In this way it has been found that the arginine-rich histones, H3 and H4, are necessary and sufficient for the generation of a nucleosome-like complex. When H3 and H4 alone are reconstituted with DNA in appropriate conditions, the resulting complex can be digested with nucleases to give subnucleosomal DNA fragments identical in size (though not in relative abundance) to those produced when nucleosomes are digested^{58,60}. Such H3–H4 complexes also show a characteristic resistance of the histones to attack by trypsin or chymotrypsin, seen also in nucleosomes⁶⁰.

Furthermore, X-ray diffraction patterns of fibres made from reconstituted complexes of DNA with H3-H4 are almost identical to those obtained from intact chromatin fibres^{61,62}. It has also been shown that these two histones alone are capable of inducing an extent of supercoiling in closed circular DNA approximately equivalent in weight (roughly twice the normal complement) to that induced by all four histones^{62,63,64}. No combination of histones that omits either H3 or H4 gives any indication of ability to induce structure^{62,68,69}.

Complexes of the arginine-rich histone pair with closed circular DNA appear in the electron microscope as a beaded string^{63,64}, although the bead diameter is somewhat smaller than that of a normal nucleosome. If DNA 140 base pairs long is used, isolated beads are seen⁶³. The beads sediment in the ultracentrifuge in a manner consistent with their compact structure^{60,63}. Though there is some debate about whether a tetramer⁶³ or an octamer⁶⁰ of H3-H4 is associated with such a folded bead, it is clear that the arginine-rich histone pair plays a central part in nucleosome formation, as first suggested by Kornberg³. The arginine-rich histones have been the most strictly conserved in amino acid sequence during evolution. They are also the most tightly bound of all the histones. The results so far obtained leave open the question of the role of the slightly lysine-rich histones, H2A and H2B, in completing the normal nucleosome structure. That role may not become apparent until more is known about the function of nucleosomes in biological processes.

Higher orders of structure

The nucleosome must also be involved in the higher orders of structure that fold the DNA into the extremely compact form found in the nucleus. Attention has been concentrated on the first two levels of organisation, a 'thin' chromatin filament, 100 Å in diameter, and a thicker fibre, with a diameter of 200–300 Å. The thin fibre is almost certainly a linear array of nucleosome cores in contact with one another. The thick fibre seems to be generated by coiling of the thin fibre.

Neutron diffraction studies of the 300 Å chromatin fibre suggest that the nucleosomes are arranged in a solenoid with a 100 Å pitch, a diameter of 300 Å and a 100 Å hole down the central axis⁶⁵. The pitch is presumably determined by the side-by-side packing of nucleosomes on adjacent turns of the solenoid. Solenoids of these dimensions are also seen in electron micrographs of nucleosome oligomers⁶⁶, but only when magnesium ion is present. In its absence, only the 100 Å thin filament is visible. It is easy to build models^{66,67} in which strings of spherical beads are packed to form the solenoidal structures, although some modification will be necessary to take into account the correct, non-spherical nucleosome shape.

There is good reason to think that interactions between nucleosomes are modified or stabilised by the lysine-rich H1 histones. These histones are bound to chromatin at least in part through attachment to the DNA spacer region between nucleosome cores. During staphylococcal nuclease digestion, H1 histone is liberated from monomer nucleosomes as the DNA size is reduced from 200 base pairs to 140 base pairs^{22,68–70}. A DNA fragment about 35 base pairs long appears simultaneously, with H1 bound to it⁷¹.

The presence of H1 may have a direct effect upon chromatin structure. For example, SV40 minichromosomes containing H1 appear as compact structures in the electron microscope. Salt extraction, which should remove H1, allows the structure to open up into the more familiar beaded forms^{72–76}. Similarly, if well fractionated nucleosome oligomers are stripped of histone H1, there is a change in the dependence of the frictional coefficient on oligomer size⁷⁰, consistent with stabilisation of compact structures by H1. Studies of the dependence of H1 binding on the size of nucleosome oligomer show that there is a steady increase in affinity up to the octanucleosome, and no further size dependence beyond that⁷⁷. This suggests that octanucleosomes are capable of forming a stable unit of higher order structure: electron micrographs of oligonucleosome fractions

containing H1 reveal the presence of spherical structures about 200 Å in diameter, which have been termed 'superbeads', and seem to contain 6 to 10 nucleosomes each⁷⁷. The relationship of these structures to the superhelically wound oligonucleosome fibres seen earlier is uncertain. It has been pointed out⁷⁷ that exposure of chromatin to very low ionic strength solvents disrupts the higher order 300 Å chromatin fibre, and disturbs the size-selective binding of H1 noted above, perhaps by disruption of cooperative H1 interactions; variations in structure may arise from such rearrangements.

It is not clear exactly how H1 contributes to compaction of oligonucleosomes. The mode of binding of H1 to either negatively or positively wound superhelical DNA is different from its binding to the relaxed circular form⁷⁸. H1 may form bridges between superhelical turns, and indeed it has recently been shown that when H1 is added to H1-depleted SV40 minichromosomes, some H1 molecules link non-adjacent nucleosomes⁷⁵. H1 molecules may also connect spacer regions on either side of a single nucleosome⁷⁹. Either mode of binding could permit H1 molecules, if their termini were close to each other, to be polymerised by chemical cross-linking reagents, a phenomenon that has been observed⁸⁰.

Of all histones, H1 has the most variation in amino acid sequence among histone subspecies, as well as the largest number of variants. It is reasonable to speculate that the size of the variable spacer region between nucleosome cores is correlated with the subspecies of H1 bound to it; there may be a relationship between the size of the spacer and the number of basic residues on the H1 molecule^{10,14}. It has also been suggested^{81,82} that variation in the amino acid composition of histones H2A and H2B^{83–85} could alter contacts between nucleosomes, and affect the size of the spacer. Whatever the determinant of the spacer length, the thin filament and higher order structures must be capable of accommodating variable lengths of DNA in the region between nucleosomes. It can be inferred from nuclease digestion studies that in at least some cases the lengths of these regions are integral multiples of ten base pairs¹⁷, and may also have regularly spaced accessible sites within them when H1 is present. Worcel⁸¹ has proposed a model of the thin chromatin filament, 100 Å in diameter, in which adjacent nucleosome cores are in contact, but the cores can be rotated with respect to one another to permit inclusion of a variable length of spacer DNA without altering the diameter of the fibre. The spacer DNA is not in close contact with core proteins, but is assumed to be complexed with H1, in a way which stabilises supercoiling of the thin filament to form a 200–300 Å fibre. Furthermore, still higher order coiled structures can be formed from this fibre in such a way that the spacer DNA is always at the outside, and accessible to nucleases.

Such models, though they may turn out to be wrong in detail, provide important tools for thinking about higher orders of structure which nucleosome packing must generate, and which we have only begun to examine experimentally.

Chromatin structure and biological activity

The information we have so far obtained about chromatin structure clearly relates to DNA packaging in the eukaryotic nucleus. There is no reason to doubt the tenet of molecular biologists that knowledge of structure leads to understanding of function; what we now know about chromatin structure is simply not enough to permit the connection to be made. Perhaps for that reason, many of the questions now being asked about the role of histones in the biological activity of chromatin are little different in form from those asked four years ago⁸⁶, except that they are cast in terms of nucleosomes rather than in terms of more poorly defined histone complexes.

The obvious first task is to find out what happens to nucleosomes during DNA replication and transcription. In the case of replication, new histones are synthesised as well as new DNA, and new nucleosomes are made. Are the new histones segregated or mixed with the old? In a recent set of experiments⁸⁷, the fate of newly synthesised histones in chick myoblasts was traced by

Fig. 4 *a*, Buoyant density centrifugation of newly synthesised histones crosslinked to form octamers. Cells were labelled for 1 h in dense amino acids and ^3H -lysine. Chromatin was prepared by mild nuclease treatment of nuclei. After crosslinking the histones with Lomant's reagent (dithiobis (succinimidyl propionate)), the sample was banded to equilibrium on a caesium formate-guanidinium chloride gradient, together with uncrosslinked, ^{14}C -lysine labelled, light histone marker. The density of the ^3H -labelled peak corresponds to octamers containing only dense amino acids. (From ref. 87.) *b*, Possible modes of assembly of newly synthesised histone octamers. The data in *a* support model C. (From ref. 87.)

pulse labelling them with ^3H -lysine and dense (^{13}C and ^{15}N labelled) amino acids. The nucleosome monomers were isolated from the cells, and the histones within each nucleosome cross-linked chemically. The crosslinked histones were freed from DNA and their density determined by isopycnic centrifugation. Although newly synthesised histone represented only one-seventh of the total histone, all the newly synthesised molecules were found to band in the fully dense position, showing that crosslinking within the octamer had not joined old and new histones to each other (Fig. 4). This demonstrates that newly synthesised histones form completely new nucleosomes, rather than forming mixed octamers with old histone.

By using modifications of this experimental approach, it is possible to show⁸⁷ that newly synthesised octamers tend to be located near other new octamers, confirming the model of non-random distribution of new nucleosomes that had been deduced earlier by less direct experimental methods^{88,89}. It can also be shown that individual histone octamers preserve their integrity (that is, segregate conservatively) through at least three or four rounds of replication⁸⁷. Other evidence suggests that such a conservative segregation mechanism governs the behaviour of long sequences of adjacent nucleosomes⁸⁷.

These experiments do not examine the way in which newly made histone interacts with newly made DNA, and in fact there are conflicting reports in the literature (see ref. 87) as to whether new histone distributes randomly, or segregates in association with new DNA. If the histone distribution is in fact non-random, the way is open to a variety of mechanisms which could, in principle, preserve the identity and sequence of nucleosomes in the chromatin of a stem cell line, while allowing diversity in daughter DNA duplexes.

Since histone octamers stay together *in vivo* through several generations, there is no need to invoke mechanisms in which the nucleosome disassembles as part of the replication process, though such mechanisms are not excluded provided that old subunits are able to find each other again. It remains to be determined how newly made nucleosomes choose the particular daughter helix to which they will bind. Whatever the role of nucleosomes in replication, it seems unlikely that their presence would result in a process simpler than that which occurs in prokaryotes⁹⁰. In studying replication in eukaryotes, it would be

reasonable to expect a complicated series of enzymatic reactions, to which nucleosomes have adapted.

Perhaps because the analogous reaction in prokaryotes is better understood, studies of chromatin transcription far outnumber studies of replication. It has proved difficult to construct a satisfactory transcription system *in vitro* that sheds light on the mechanism *in vivo*, partly because the mode of action of eukaryotic RNA polymerases is not well known. The prominent exception is the system for transcription of the 5S RNA genes of *Xenopus in vitro*. Roeder and his colleagues⁹¹ have shown that selective asymmetrical transcription of the 5S gene can be achieved, provided that the proper polymerase is used (that is the class III eukaryotic RNA polymerase, responsible for 5S gene transcription *in vivo*), and provided that the template is chromatin rather than protein-free DNA. Recent results⁹² suggest that reconstituted chromatin may be effective as a template, furnishing a tool for studying the role of the various components of chromatin in regulating transcription of these genes.

Most investigations of chromatin transcription *in vitro* have used bacterial RNA polymerase, and should be regarded as studies not of transcription, but of chromatin structure, using the polymerase as a probe. Although there have been numerous reports of selective gene-specific transcription of chromatin by bacterial polymerase, the approach has not so far yielded a great deal of information about chromatin structure, probably because the methods used are tedious and subject to numerous potential artefacts⁹³⁻⁹⁵. It has recently been found, for example, that when endogenous mRNA is present as a contaminant in chromatin preparations, it can be used as a template by *E. coli* RNA polymerase to make an RNA strand complementary to the message, which forms a duplex with it^{94,95}. Certain techniques for distinguishing and isolating newly made RNA, such as incorporation of mercury-substituted nucleoside triphosphates, will lead to isolation of the duplex, and hence accidental purification of the endogenous message^{94,95}. The endogenous message sequences will subsequently be detected in the assay and ascribed erroneously to synthesis *de novo*. Complications such as these have made it difficult to use bacterial RNA polymerases as probes of chromatin structure.

How can we obtain more information about chromatin

structure in the neighbourhood of a transcriptionally active gene? One useful approach is to ask whether the structure is like that of the bulk of chromatin with respect to its sensitivity to nuclease. The answer that is obtained depends upon the nuclease that is used.

When staphylococcal nuclease is used to digest transcriptionally active, non-ribosomal genes, the pattern of products is very similar to that generated by this enzyme when it attacks the bulk of chromatin. For example, globin genes in avian reticulocytes are protected against exhaustive digestion by staphylococcal nuclease to the same extent as all other chromatin DNA^{50,96,97}. This parallel behaviour is also observed earlier in digestion: Lacy and Axel⁹⁸ have isolated nucleosome monomers, sedimenting at 11S, from partial staphylococcal nuclease digests of avian reticulocyte nuclei, and find that the abundance of globin gene sequences in the DNA of this fraction is identical to the genomic abundance. Thus the globin genes in reticulocytes, which are active in producing globin mRNA, are packaged in structures possessing the same repeat as the nucleosome. Similar results have been obtained⁹⁹ for the abundance of ovalbumin sequences in purified nucleoprotein monomers from hen oviduct nuclei.

The distribution of ovalbumin sequences has also been examined by fractionating the partly digested nuclear DNA rather than the nucleoprotein oligomers¹⁰⁰. Early in digestion, most of the ovalbumin genes are present in DNA fragments that are multiples of a subunit about 200 base pairs long. But, the monomer DNA fraction is preferentially enriched in ovalbumin sequences. The apparent inconsistency with the earlier observations⁹⁹ that 11S nucleoprotein monomers are not similarly enriched would be resolved if some ovalbumin sequences 200 base pairs long were not derived from 11S particles. Proof of this hypothesis will require a careful accounting for the fate of all ovalbumin genes, both as monomer DNA and nucleoprotein, in the course of the digestion.

susceptibility of chromatin from adenovirus-transformed hamster cells, the easily digestible adenovirus sequences seem to correspond to that portion of the virus from which mRNA is transcribed; the other viral sequences are resistant.

These results reveal a correlation between DNaseI sensitivity and a potential for or history of gene activity. Response to the nuclease does not necessarily depend upon how often the gene is being transcribed. For example, the globin gene retains its sensitivity in blood cells from 18-d-old chick embryos⁹⁷, in which globin message synthesis has largely ceased. Similarly, gene sequences that are infrequently represented in the mRNA population are nonetheless DNase sensitive⁹⁸. If it is assumed that the abundance of an mRNA sequence reflects the number of RNA polymerase molecules bound to the corresponding DNA, it can be concluded that it is not the transcription complex that confers special sensitivity to pancreatic DNase. We do not know whether the structural differences detected by this enzyme are a cause or an effect of transcription.

What kinds of structure could confer such sensitivity? Protein-free DNA might be digested preferentially. However, the same sequences that are digested by DNaseI are resistant to staphylococcal nuclease in a way which indicates that proteins are present. It should be emphasised that the absence of preferential digestion by staphylococcal nuclease is not necessarily diagnostic of the presence of protein. For example, at very low ionic strength, the kinetic constants describing the action of this enzyme on chromatin and on naked DNA⁸⁰ are such that, in substrate excess, mixtures of chromatin and DNA will be digested at approximately equal rates. Thus, experiments which merely test the initial rate of digestion of a sequence may not, in certain conditions, distinguish between chromatin and DNA. For these reasons, the crucial observations with staphylococcal nuclease are the appearance of most of the transcriptionally active sequences in nucleosome-like repeats, and the appearance of the genomic abundance of these sequences in

Fig. 5 Electron micrographs of chromatin from *Oncopeltus fasciatus*, enlarged about 67000 \times . *a*, Beaded chromatin from regions devoid of ribonucleoprotein (RNP) fibres. *b*, Beaded chromatin between nascent non-ribosomal RNP. *c*, Unbeaded chromatin of newly induced ribosomal transcription units. (From ref. 106.)

In contrast to the results with staphylococcal nuclease, the response of transcriptionally active sequences to digestion by pancreatic DNase (DNaseI) is strikingly different from that of normal chromatin. As first reported by Weintraub and Groudine⁹⁷, and subsequently confirmed in a number of laboratories, DNA sequences corresponding to active genes are digested preferentially. The list of susceptible sequences includes the globin gene in chick erythrocytes⁹⁷, the ovalbumin gene in hen oviduct¹⁰¹, and endogenous avian tumour virus sequences in chicken DNA⁹⁷. In a similar study¹⁰² of the pancreatic DNase

'limit digests'^{50,96}, which contain only fragments of subnucleosome size. The former observation shows that the DNaseI sensitive regions are packaged with proteins in a way that at least mimics nucleosomes; the latter observation strongly suggests that the proteins in question are indeed the nucleosomal complement of histones. To reconcile this conclusion with the observed sensitivity to pancreatic DNase, it must be assumed⁹⁷ that the nucleosome structure is modified or opened in a way that permits pancreatic DNase, but not staphylococcal nuclease, to detect the difference.

It should be noted that although the pattern of sensitivity described above has been observed for most of the active genes so far examined, there are exceptions. At least one integrated viral sequence has been found to be sensitive to both pancreatic DNase and staphylococcal nuclease¹⁰³. There is also some evidence both from nuclease digestion¹⁰⁴ studies and electron microscopy that actively transcribed ribosomal genes may not be like the other active genes discussed above. Ribosomal genes that are undergoing transcription are identified easily in the electron microscope by the characteristic tree-like structures formed by the growing ribonucleoprotein fibres, which extend from the DNA¹⁰⁵. Unlike the bulk of chromatin, no 'beads' are visible on these genes. Furthermore, since the length of DNA in each ribosomal gene is known, the DNA packing ratio can be measured, and it is found to be 1.2 (refs 106 and 107). Thus, the DNA of the transcribed ribosomal genes is only slightly less extended than normal protein free-DNA. This does not mean that proteins are necessarily absent from the ribosomal genes, since the mean diameter of the ribosomal chromatin fibre is about 73 Å.

Electron microscopists have also examined non-ribosomal genes undergoing transcription. Although subunit structure is not always visible¹⁰⁸, there are at least some cases in which a beaded structure has been reported¹⁰⁹. The difficult step in such observations is the identification of the active region. A tree-like structure of growing ribonucleoprotein chains can be found, and although it is less regular than the structure found on ribosomal genes, a convincing argument can be made that the chains arise from transcription of a delimited segment of DNA¹⁰⁶. Examination of these non-ribosomal 'transcription units' reveals the presence of beaded structures on the chromatin between ribonucleoprotein chains (Fig. 5). The diameter of these beads, about 13.5 nm, is similar to that found for nucleosomes under similar preparative conditions. The number of beads per unit length of chromatin within the transcription unit is about 70% that found in the bulk of chromatin¹⁰⁶. Recent experiments have shown that these regions react with antibodies to histones H2B and H3¹⁰⁹.

The electron microscope studies support many of the conclusions derived from the nuclease digestion experiments, but have not so far revealed the structural basis of sensitivity to pancreatic DNase. The sensitivity could arise from an alteration within each core particle (for example, to permit formation of half-nucleosomes), perhaps as a result of chemical modification of the histones, or it could reflect a perturbation of the higher-order packing of the nucleosomes, perhaps connected with loss or modification of histone H1 molecules.

The view we presently have of chromatin structure is still largely static. We do not yet understand any of the many conformational changes that must take place during the cell cycle both in individual nucleosomes, and in the higher order structures they form. Some of these changes may arise from modifications in composition. We know that the histones are chemically modified at various times during the cell cycle. Furthermore, during development, subspecies of certain histones are synthesised that differ slightly in amino acid sequence^{83,84} and might function differently in the nucleosome. Chromatin structure must also involve components that have been excluded from this discussion: the proteins that are not histones. The so-called high-mobility group (HMG) proteins¹¹⁰, for example, are found in abundance associated with chromatin¹¹¹. Another protein, ubiquitin, is found covalently coupled by an isopeptide linkage to histone H2A, in some cases modifying one in five H2A molecules^{112,113}. There are many other proteins, among them the polymerases themselves, that react with and may modify chromatin structure, and we may suppose that there are smaller molecules as well that have that capability. As we begin to understand the chemistry of these many reactions, the relationship between structure and mechanism may emerge.

I thank many colleagues for providing copies of manuscripts in advance of publication and Dr D. Camerini-Otero, Dr M.

Gellert, Dr J. McGhee and Dr M. Zasloff for their critical comments.

Volume and extent of the Minoan tephra from Santorini Volcano: new evidence from deep-sea sediment cores

N. D. Watkins, R. S. J. Sparks, H. Sigurdsson, T. C. Huang, A. Federman, S. Carey, & D. Ninkovich*

Graduate School of Oceanography, University of Rhode Island, Kingston, Rhode Island 02881

Analyses of tephra in abyssal piston cores collected during cruises of R/V Trident show that the Minoan eruption produced at least 28 km³ of tephra (13 km³ dense rock equivalent). A layer up to 5 cm thick must have been deposited on eastern Crete.

THE great Bronze Age eruption of Santorini (Thera) in the Hellenic arc is one of the largest known explosive eruptions in post-glacial time. The eruption, which occurred approximately 1500 BC, led to widespread tephra-fall in the Eastern Mediterranean and resulted in the formation of a caldera with an area covering 83 km² and a depth of 600–800 m. Apart from its volcanological significance, this Bronze Age eruption acquired added archaeological importance after Marinatos¹ advanced the theory that the wide-spread Late Minoan destruction on Crete was a consequence of the paroxysmal volcanic events on Santorini. The discovery of Minoan volcanic tephra in a few deep-sea sediment cores from the Eastern Mediterranean² demonstrated the large magnitude of the eruption and the extent of the tephra-fall, and excited closer examination of Marinatos' theory¹. In September 1975, 32 piston cores were collected from the Aegean Sea and parts of the Eastern Mediterranean (Fig. 1) during Cruise 172 of the RV Trident. These coring traverses were designed specifically to study the distribution and dispersal of tephra downwind from Santorini volcano. We report here results of our study on the Minoan ash layer which provide new evidence on the magnitude and effects of the eruption.

*Present address: Lamont-Doherty Geological Observatory Columbia, University Palisades, New York 10964

Correlation and distribution of the Minoan tephra

The locations of the new cores, together with cores containing Minoan tephra from RV Trident Cruise 171 and Vema Cruise 10 are shown in Fig. 1a. The thicknesses of megascopically visible Minoan tephra layers are added together with isopach contours. Visible Minoan tephra was observed in 18 of the new cores. We have correlated the tephra layers not only from core to core, but also with the Minoan tephra sequence on Santorini itself by electron microprobe analyses of glass shards and pumice clasts. Table 1 shows mean analyses of the Minoan tephra as sampled on Santorini and mean analyses of glass shards from the Minoan layer in abyssal cores collected during the cruises of RV Trident and RV Vema. Figure 2a shows plots of FeO*–K₂O–CaO + MgO of microprobe analyses of glass in six of the largest pyroclastic deposits exposed in the caldera wall of Santorini. Figure 2b shows the same plots for five prominent megascopically visible tephra layers in the Trident and Vema core V10-58. We have also analysed many other smaller, less widespread layers on Santorini and in the cores and the Minoan tephra is always distinguishable on major element glass chemistry. The data in Table 1 and the figure demonstrate clearly that the major element glass chemistry of the Minoan tephra is sufficiently distinctive to facilitate easy identification of the ash. The data provide unambiguous intercore correlations and confirm earlier correlations^{2,3}. Doubts about the correlation of the Minoan tephra in deep-sea cores can now be discounted^{4,5}.

Our results on measured thicknesses of the Minoan tephra layer in the deep-sea cores are presented in an isopach map in Fig. 1a. The isopach contours are based principally on the observed thicknesses in the cores. We stress that the contours in Fig. 1a

depict minimum present-day thickness of compacted megascopic tephra layers in the cores. The new data indicate an easterly to southeasterly dispersal of the tephra with the fall-out axis passing through Karpathos. An even more easterly trend of the axis cannot be ruled out, however, on the basis of the present evidence. Isopach studies of the initial plinian deposit on Santorini itself⁶ have previously indicated a southeast to east-southeast dispersal during the early stages of the eruption. The direction of the

dispersal axis has been further confirmed by our continuing grain size studies of the tephra: the coarsest grain size in a tephra layer at a given distance from the source occurs close to our inferred axis (such as core 172-9) and the size decreases southwards. The extent of the tephra dispersal to the north is unknown due to lack of cores, but our data clearly show that some tephra-fall occurred on Crete and that the recent suggestion that the fall on Crete was negligible⁵ is untenable.

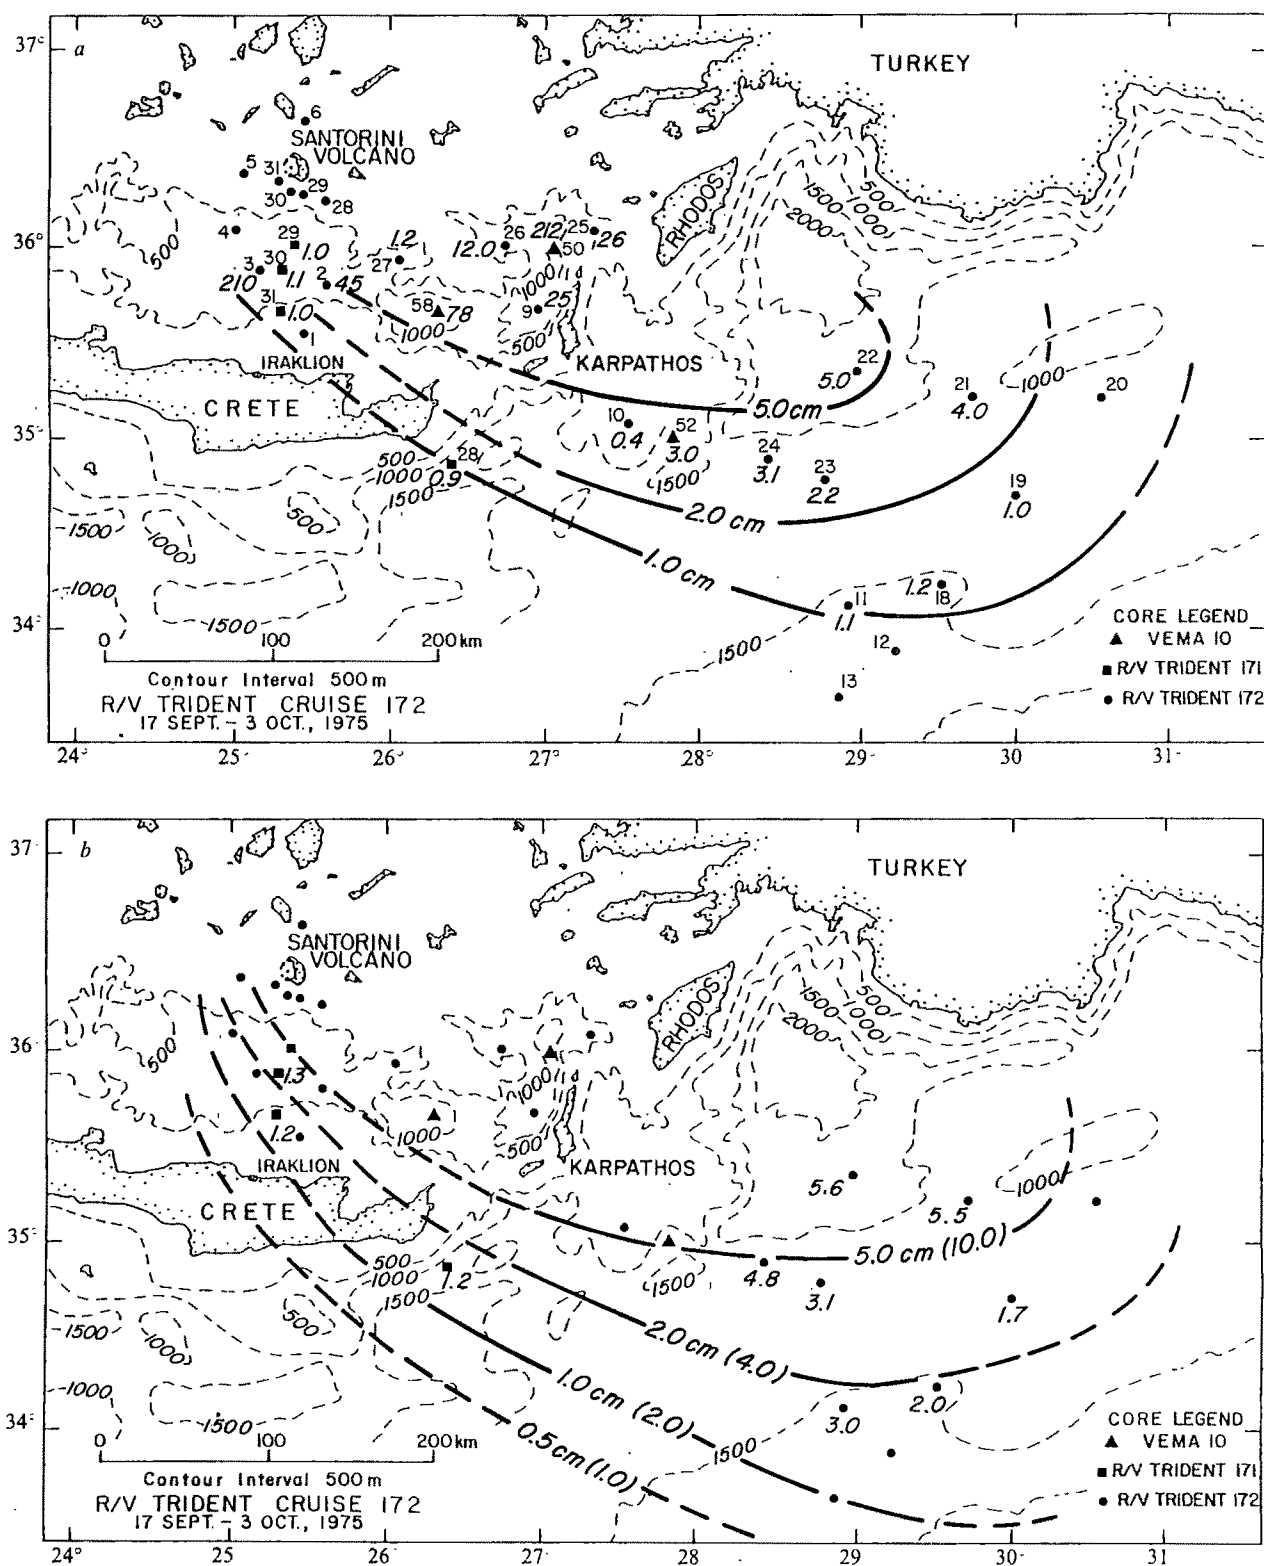

Fig. 1 Isopach maps of the Minoan tephra in Eastern Mediterranean cores. Isopachs are based on (a) the observed thickness (in cm) in the cores and (b) the adjusted thickness (in cm) to include the effects of tephra dispersal due to bioturbation. Note that in (a) the core numbers are given by small letters and the observed thicknesses in large letters. In (b) the numbers in parentheses on the isopach contours represent the thicknesses of freshly fallen tephra (before compaction) on land which are approximately twice those observed in the cores.

Fig. 2 FeO* (total iron) – K₂O – CaO + MgO plots of analyses of glass in tephra deposits from the Hellenic Island Arc. *a*, Six of the prominent pyroclastic layers in the caldera wall of Santorini are shown including the Minoan tephra layer. Each field is based on at least 10 analyses. *b*, Five widespread tephra layers found in cores from the Eastern Mediterranean are shown. The Minoan layer can be readily distinguished from the older Y-4 layer⁹ although the refractive indices are indistinguishable. Each field is defined by at least 12 analyses. The Minoan field in *a* coincides with that in *b*.

The RV Albatross cores collected by the Swedish Deep-sea Expedition⁷ are excluded from our data as we have been unable to obtain samples to correlate the alleged Minoan tephra layers in these cores. There is clearly some doubt over the correlations in the RV Albatross cores⁴: for example, core 192 south of Crete has a tephra layer in the upper part of the core with a thickness of 4 cm (refs 2,7) and has influenced previous reconstructions of tephra distribution and estimates of tephra thickness on Crete. This core lacks the distinctive 7,000 yr BP sapropel characteristic of many cores in the Eastern Mediterranean⁸. The stratigraphy in this core is therefore quite atypical of the strata associated with the authenticated Minoan tephra layer, but similar to the stratigraphy of tephra layers older than the 7,000 yr BP sapropel. An extensive tephra layer, known as Y-4 (after the recent stratigraphic nomenclature of Keller and others⁹), occurs beneath the sapropel in several cores and has a similar refractive index to the Minoan glass (1,508 ± 0.003). This layer, however is different chemically (Fig. 2*b*). The upper layer in the RV Albatross cores could equally well be the Y-4 layer if the upper parts of the cores are missing. Because of these uncertainties we exclude these cores until unambiguous correlations for tephra in the Albatross cores are produced.

Controls on tephra thickness

Tephra layer thicknesses have to be interpreted with caution as both volcanic and marine processes may control the ultimate thickness observed in a core. At least three important marine processes modify tephra thicknesses: sediment-ponding, bioturbation and compaction. When a large volume of loose tephra accumulates during an eruption, slumping may occur to generate turbidity currents, grain flows and debris flows. The consequence of such sediment-ponding processes¹⁰ is an increase in layer thicknesses in basins and to thin or erase layers on submarine topographic highs and steep slopes. Bioturbation of tephra layers mixes the tephra with other sediments and can reduce visible tephra layer thicknesses, dispersing tephra in the overlying sediment. Finally post-depositional compaction can substantially reduce the thickness of the tephra layer compared to the freshly-fallen thickness.

Within the Aegean Sea the great thicknesses within the basins are due to repeated slumping during the eruption to produce successive turbidite units. Evidence for turbidite origin includes erosional bases and partial Bouma sequences, including graded tephra beds. Figure 3 shows the lithology of several units within the Minoan tephra layer in core 172-9 as well as profiles of carbonate and clay content, median grain diameter, and pumice, lithic and crystal contents. The two layers labelled D are both interpreted as turbidites as they contain abundant carbonate, clay and some rounded terrigenous quartz grains, mixed in with the tephra. By contrast the tephra layer in core 172-27 (Fig. 1*a*), for example, is only 1.2 cm in thickness despite the fact that the core is

only 80 km away and lies close to our suggested dispersal axis. This core is located on a steep slope and we attribute thinning of the layer in TR 172-27 to the slumping or erosion of much of the tephra. For these reasons none of the measured thicknesses of the Minoan tephra within the Aegean Sea have been used in our construction of isopach contours.

Bioturbation affects most tephra layers, but is of particular importance outside the Aegean Sea where the tephra layer becomes relatively thin. Using our technique¹¹ we have quantitatively analysed the dispersed tephra in continuous samples taken above and below the visible tephra layer in 11 selected cores. The volume of dispersed tephra has been determined and its equivalent thickness added to the thicknesses of visible ash in each core. Up to 65% of original tephra has been mixed upward by bioturbation. In the Indian Ocean a 15 cm ash layer from Toba west of Sumatra has lost some 5 cm of ash by bioturbation into overlying sediment¹² emphasising the importance of this process. Fig. 1*b* shows the corrected tephra thicknesses and revised isopach contours. Comparison of Fig. 1*a* and 1*b* illustrates that tephra layer thicknesses can be markedly altered by bioturbation. While the reconstruction does not alter the basic dispersal pattern of the Minoan tephra, the corrections clearly make a substantial difference to volume estimates.

The thickness of a compacted tephra layer in a deep-sea core is considerably less than the thickness of freshly fallen tephra on land. We have studied the effect of post-depositional compaction on tephra layer thickness by experimental resedimentation of dry Minoan tephra from the cores. The results of three experiments in air show that the compacted tephra layers are equivalent to only approximately 50% of the thickness of resedimented dry tephra of equivalent weight and grain size. These results are in close agreement with our findings on the 1902 tephra of the Soufriere of St Vincent¹³. This eruption resulted in 10 mm of tephra fall on Barbados, whereas gravity cores recovered a 5-mm tephra layer in the adjacent Tobago Trough. Thorarinsson¹⁴ has reported similar relations from historic tephra layers in Iceland. In Fig. 1*b* we also show our estimates of the original thicknesses of freshly fallen tephra and reconstructed isopach contours. This procedure reveals the likely thicknesses of tephra on Crete and adjacent islands, although other factors causing tephra compaction under the deep-sea environments were not taken into account.

Eruption sequence and tephra volume estimates

Volcanological considerations prevent simplistic interpretations of the data. Recent studies of the Minoan deposits on Santorini^{6,15} indicate three main phases in the eruption: (1) the plinian phase producing a coarse tephra fall deposit; (2) a phase of phreatomagmatic activity producing interstratified fine grained and poorly-sorted tephra fall deposits and base surge horizons overlain by mud-flow deposits; and (3) a pyroclastic flow phase producing many non-welded ignimbrite flow units, intra-formatinal flood deposits and very fine grained co-ignimbrite

Table 1 Microprobe analyses of glass in Minoan tephra from Santorini and the deep-sea cores

Oxide	Tephra on land	σ	Tephra in cores	σ
SiO ₂	70.60	(0.18)	71.40	(0.10)
Al ₂ O ₃	13.60	(0.06)	13.50	(0.14)
FeO*	1.74	(0.06)	1.74	(0.05)
MgO	0.24	(0.02)	0.25	(0.02)
CaO	1.35	(0.01)	1.32	(0.05)
K ₂ O	3.12	(0.04)	3.19	(0.06)
Na ₂ O	5.07		4.98	
TiO ₂	0.26	(0.02)	0.27	(0.01)
Total	95.98		96.65	

The table shows the mean of six analyses for the land-based sample, and the mean of three analyses for the samples from cores, together with the standard deviation (σ) for each element oxide. All are expressed in weight %. Total iron is expressed as FeO*. All analyses were performed on a JEOL JXA-50A electron microprobe, with accelerating voltage of 15 kV, beam current of 0.0125 μ A, specimen current of 0.0100 μ A, and a beam diameter of 5–10 μ m. The rate of sodium loss during analysis was measured as 50% of original concentration in 30 s. The quoted values for sodium have been corrected accordingly.

tephra fall deposits¹⁶. Each of these phases produced a vertical convective eruption column and air-fall ejecta from each phase probably has its own dispersal pattern and grain size characteristics. Complexities in tephra dispersal have been observed in other eruptions such as Karmai (1912)¹⁷ and the Mount Mazama eruption, Crater Lake, Oregon¹⁸, which formed products comparable to the Minoan Eruption.

The tephra layer in core 172-9 (Fig. 3) compares with the stratigraphy observed on Santorini. A coarse, ungraded, well-sorted crystal-rich layer, 3.5 cm thick (B in Fig. 3) occurs at the base with a sharp upper boundary and is overlain by several fine grained layers (C-F). Two of the normally graded layers with erosional basal boundaries (Interval D) are turbidites. Evidence of mixing with local sediment is absent in layer B and it is interpreted as a primary air-fall layer buried by the turbidites and later fine-grained tephra fall. Although 165 km from source layer B lacks the fine grain sizes which are abundantly present in the tephra fall layers produced by phases (2) and (3) on Santorini itself⁶. Thus layer B is interpreted as correlating directly with the plinian layer (phase 1) on Santorini whereas the upper layers are predominantly composed of phase (2) and (3) ejecta probably mixed with minor amounts of phase (1) material during slumping.

Figure 4 shows the relation between thickness and distance in several well-documented eruptions together with the estimated volume of tephra in each case^{14,18-21}. If layer B (Fig. 3) represents the primary thickness of the plinian layer an approximate curve can be drawn for the Santorini plinian deposit, using the near source data⁶ and core TR 172-9. The plinian deposit falls between the Toluca deposit¹⁹ in Mexico and the Mount Mazama plinian deposit, Oregon¹⁸, suggesting an approximate volume of

Fig. 3 Lithology of the Minoan tephra layer in core TR 172-9 showing sediment-ponding processes. From bottom to top: a, grain-flow deposit; b, plinian air-fall layer; c, fine tephra-fall unit; d, two repeated ash turbidites; e, and f, laminated tephra layers winnowed by bottom currents and g, pelagic muds admixed with tephra. Percent carbonate and clay, median grain size ($Md\phi$) and the weight percentage of pumice and glass shards (clear), lithics (hatched) and crystals (stippled) in grain size fractions greater than $63\ \mu\text{m}$.

5–8 km³ for the ejecta in this phase. To the east of Karpathos the tephra layer in all cores consists of a single layer and evidence of a multiphase eruption is absent. One possibility is that the plinian layer has thinned to such an extent that it is undetectable or even absent. The tephra layers at 350–500 km distance would then represent the equivalent of phases (ii) and (iii) of the eruption.

Whether or not the above interpretations are correct, the thicknesses east of Karpathos can be used extrapolated back to Santorini to give an approximate guide to the overall magnitude of the eruption, and to indicate the possible location of isopach contours in the Aegean (Fig. 4). The maximum thickness of all the air-fall layers on Santorini is about 15 m. This estimate is for the air-fall components of all three phases: individually the plinian pumice layer has a maximum thickness of 5.5 m, the fine-grained

Fig. 4 Relationship between thickness and distance from source along the dispersal axis in several tephra fall layers, for comparison with the Minoan layer. Volumes of ejecta reported by the authors on each layer are Hekla¹⁴: 0.17 km³; Avellino pumice deposit, Vesuvius²⁰: 2.1 km³; Toluca deposit, Mexico¹⁹: 3.5 km³; Crater Lake airfall deposit, Oregon¹⁸: 15 km³; White River Ash²¹: 25 km³; Minoan tephra: 28 km³. Curves are shown for the Minoan plinian deposit (●), based on the interpretation of TR172-9 and for the compacted thickness of the total Minoan tephra layer (▲) using the adjusted isopach contours in Fig. 1b.

air-fall and base surge ashes a maximum thickness of 6.5 m and the co-ignimbrite air-fall ash deposits a maximum thickness of 3 m. We have used the data in Fig. 1b and the approximate distance/thickness curve in Fig. 4 to estimate the volume of tephra. We have assumed that the dispersal axis passes through Karpathos and that the volume of ejecta south of the axis is matched by an equivalent volume north of the axis. The volume of tephra on Santorini itself, assuming an average thickness of all tephra of 15 m over 200 km², is 3 km³ and we estimate the total minimum volume of the compacted deposit to be 28 km³, within the 0.5 isopach contour. We note that had we just used the uncorrected data in Fig. 1a the volume estimate would only have been 23 km³.

The bulk density of the abyssal tephra was determined as 1.0 g cm⁻³. The density of the original magma was calculated at 2.2 g cm⁻³ using the method of Bottinga and Weill²² for the average glass composition at a temperature of 850 °C, taking into account the 10% phenocrysts in the original melt and assuming a water content of 3.0%. Thus the dense rock equivalent volume (DRE) is estimated at 13 km³. There is a substantial discrepancy between the DRE volume and the volume required to account for the caldera (60 km³). We stress, however, that our estimate is very much a minimum for several reasons. Firstly, the volume outside the 0.5 cm isopach may be substantial; furthermore, the volume north of the dispersal axis is unconstrained simply because of insufficient data coverage and the axis could well be further north, leading to increased volume estimates. Finally a considerable proportion of the magma is believed to have been erupted as pyroclastic flows⁶ which formed substantial accumulations of tephra transported by turbidity currents into the basins surrounding Santorini. The number of available cores and their poor penetration close to Santorini is insufficient to estimate the volume of pyroclastic flow material.

Effects of the eruption on the Minoan civilisation

The new data provide improved constraints on the thickness of tephra which could have fallen on Crete. Figure 1b illustrates that the freshly fallen thickness probably fell in the range 0–5 cm. In eastern Crete, where the majority of Late Minoan settlements occurred²³, the thickness must have been between 1 and 5 cm depending on the locality. Very much greater thicknesses or very much less would be very difficult to reconcile with the data, and present understanding of tephra fall-out patterns. Such tephra thicknesses would undoubtedly have been an inconvenience to the Minoan population and could have produced some minor agricultural damage which may have been moderately severe in the extreme northeastern part of the island. Thorarinsson¹⁴ has documented that greater than 10 cm of freshly fallen tephra resulted in the abandonment of farms in Icelandic eruptions. We note, however, that agricultural techniques in Minoan times may have been less able to cope with tephra-fall than in more recent times.

Our data suggests that the Minoan colonies on Rhodes and the south coast of Turkey may have suffered severe tephra-fall, whereas tephra-fall on Crete was probably insufficient in itself to cause a major decline of the Minoan Civilisation. We emphasise that our data does not, however, preclude a relationship between the eruption and the demise of the Minoan Civilisation. Present understanding of the direct effects (for example, tephra-fall) and indirect effects (for example, tsunamis, earthquakes and meteorological phenomena) of very large explosive eruptions is very limited, as eruptions of this magnitude are yet to be chronicled.

Tumour-specific phenylalanine tRNA contains two supernumerary methylated bases

Yoshiyuki Kuchino* & Ernest Borek

Department of Microbiology, University of Colorado Medical Center, Denver, Colorado 80262

Every malignant tumour examined contains aberrant tRNA methyltransferases and a few tRNAs which are absent from the normal tissue of origin. To determine whether tumour-specific tRNAs have different modifications from those in normal tissue, we purified the most frequently occurring tumour-specific isoaccepting tRNA from two malignant tissues. The isoaccepting phenylalanine tRNA from Novikoff hepatoma and Ehrlich ascites cells both contain two supernumerary methylated bases. One of these 1-methylguanine, is absent from the phenylalanine tRNA of normal rat, mouse, rabbit and calf liver. An increase in the levels of 5-methylcytidine and dihydrouridine was also detected.

THE tRNA methyltransferases are aberrantly hyperactive in every malignant tumour examined and in each there are a few altered isoaccepting tRNAs which are absent from the tissue of origin¹. Whether the tumour-specific tRNAs differ in primary sequence or in modification has remained obscure. An analysis of the base sequence and of the modified bases in a pure, tumour-specific tRNA could establish the genesis of the altered tRNAs. If the primary sequence is found to be altered, it would imply that the tRNA originated either from a different or a mutated gene, or from error-prone transcription. If the primary sequence is unaltered, but some modifications are either absent or are supernumerary, then the tumour-specific tRNA is the product of aberrant modification.

There are conflicting reports in the literature about the modified base content of tRNAs in tumour tissue. Such confusion is not unexpected because until now, all the analyses have been performed on bulk tRNA and since most of the tRNAs in tumour tissue are identical to those of their normal counterparts, any changes in the few

tumour-specific tRNAs may be masked by the composition of the normal preponderant species.

Inspection of the literature reveals that the most frequently altered tRNA in tumour tissue is tRNA^{Phe}; therefore we undertook the purification of this tumour-specific tRNA from two different neoplasms, to compare

Fig. 1 BD-cellulose column chromatography of Novikoff hepatoma tRNA. The column (2×100 cm) was previously washed with 0.02 M sodium acetate buffer (pH 6.0) and 0.2 M NaCl. Novikoff hepatoma tRNA (10,000 A₂₆₀ units) was applied to the column. A linear gradient elution was carried out using 1 l of 0.02 M sodium acetate buffer (pH 6.0) and 0.5 M NaCl in the mixing chamber, and 1 l of 0.02 M sodium acetate buffer (pH 6.0) and 1.5 M NaCl in the reservoir. The column was washed finally with 0.02 M sodium acetate buffer (pH 6.0), 2 M NaCl and 20% v/v of ethyl alcohol. A volume of 10 ml of the effluent was collected per tube. —, Absorbance at 260 nm; ○, ³H-phenylalanine acceptor capacity.

the base composition of it with that of pure tRNA^{Phe} from normal tissues.

Normal mammalian tRNA^{Phe} contains a highly modified hydrophobic base (O₂Y-Wye) (peroxywybutine) which is located adjacent to the 3' end of the anticodon^{2,3}. Consequently this tRNA has a unique behaviour on benzoylated DEAE-cellulose (BD-cellulose), since it is retained much longer than other tRNAs (ref. 3). Isolation of this tRNA is, therefore, relatively easy. The elution behaviour of tRNA^{Phe} from the tumours was found to differ from their normal counterpart, so a more elaborate purification procedure had to be devised.

Purification of tRNA^{Phe} from liver

Normal rat and mouse liver tRNA^{Phe} were eluted as a single peak from a BD-cellulose column at 2 M NaCl concentration containing 20% ethanol. Normal rat liver tRNA^{Phe} was further purified by fractionation on a RPC-5 column. A single peak of tRNA^{Phe} was observed and the

Fig. 2 Further purification of Novikoff hepatoma tRNA^{Phe} on a RPC-5 column. The column (1 × 50 cm) was previously washed with 0.01 M sodium acetate buffer (pH 4.7), 0.01 M MgCl₂, 2 mM β-mercaptoethanol and 0.4 M NaCl. The tRNA^{Phe}-rich region (750 *A*₂₆₀ units) obtained from a DEAE-Sephadex A-50 column (fractions 66–91, Fig. 1) was applied to the column. A linear gradient elution was carried out using 500 ml of 0.01 M sodium acetate buffer (pH 4.7), 0.01 M MgCl₂, 2 mM β-mercaptoethanol and 0.5 M NaCl in the mixing chamber, and 500 ml of 0.01 M sodium acetate buffer (pH 4.7), 0.01 M MgCl₂, 2 mM β-mercaptoethanol and 0.8 M NaCl in the reservoir. A volume of 5 ml of the effluent was collected per tube. —, Absorbance at 260 nm; ○, ³H-phenylalanine.

tRNA^{Phe} obtained from this column had an acceptance capacity of 1.36 nmol of phenylalanine per *A*₂₆₀ unit, indicating 82% purity. Purification of normal mouse liver tRNA^{Phe} was carried out using the same methods as on rat liver tRNA^{Phe}. Normal mouse liver tRNA^{Phe} purified this way accepted 1.51 nmol of phenylalanine per *A*₂₆₀ unit of tRNA, indicating 91% purity.

Fig. 3 Rechromatography of Novikoff hepatoma tRNA^{Phe} on a RPC-5 column. The conditions for chromatography were as in Fig. 2 except that 150 ml of the same acetate buffer in each chamber was used for elution. The tRNA^{Phe}-rich region (14 *A*₂₆₀ units) obtained from a RPC-5 column (fractions 76–95, Fig. 2) was applied to the column (0.6 × 30 cm). Each fraction contained 2 ml of the effluent. —, Absorbance at 260 nm; ○, ³H-phenylalanine acceptor capacity.

Purification of tumour-specific tRNA^{Phe} from two malignant tissues

Bulk tRNA was isolated from 1 kg of Novikoff hepatoma and was fractionated on a benzoylated DEAE-cellulose column by previously described methods^{4–6} (Fig. 1). The first minor peak, which was not detected on chromatography of normal rat liver tRNA, was further fractionated on a DEAE-Sephadex A-50 column. It eluted as a single peak and was further purified on a RPC-5 column. As seen in Fig. 2, the tRNA^{Phe} was resolved into at least three peaks. The last major tRNA^{Phe} (fractions 76–95) was rechromatographed on the same column (Fig. 3). Fractions 75–86 were pooled and precipitated by adding 0.1 vol 1 M

Fig. 4 Elution profile of phenylalanyl-tRNA of Novikoff hepatoma and normal rat liver on a RPC-5 column. ³H- or ¹⁴C-labelled phenylalanyl-tRNA was prepared by previously described methods⁷. Novikoff hepatoma aminoacyl-tRNA synthetase was used to charge the tRNA. The conditions for chromatography were as described previously⁷ except that a linear gradient of 0.5–0.85 M NaCl was used. *a*, ³H-Phenylalanyl-tRNA from unfractionated Novikoff hepatoma tRNA (○) and ¹⁴C-phenylalanyl-tRNA from unfractionated normal rat liver tRNA (●). *b*, ³H-phenylalanyl-tRNA purified from Novikoff hepatoma (—) and ¹⁴C-phenylalanyl-tRNA^{Phe} from unfractionated Novikoff hepatoma tRNA (○).

Table 1 Molar ratio of nucleosides of tRNA ^{Phe}						
Base	Mouse liver	Ehrlich ascites cells	Rat liver	Novikoff hepatoma	Rabbit* liver	Calf* liver
hu	2.7	4.0	3.1	4.2	2.2	3

The tritium-labelled chromatographically separated trialcohols (as in Figs 5 and 6) were scraped from the plates, counted and their relative abundance calculated, assuming 1 mol of m₂²G per tRNA. That such an assumption is valid is indicated by the number of mol of nucleosides found: they range from 74 in tRNA^{Phe} from rat liver to 87 in Novikoff hepatoma. If two m₂²G were present, the number of mol of nucleosides would be twice those values.

* These data from ref. 9.

sodium acetate and 2.5 vol ethanol. Purified Novikoff hepatoma tRNA^{Phe} accepted 1.33 nmol phenylalanine per A₂₆₀ unit, indicating 80% purity.

Figure 4a shows the cochromatography on a reverse phase column (RPC-5) of phe-tRNA^{Phe} from unfractionated normal rat liver tRNA and from unfractionated Novikoff hepatoma tRNA. The cochromatography of the purified

phe-tRNA^{Phe} from Novikoff hepatoma (early eluting) with the unfractionated material is shown in Fig. 4b.

Bulk tRNA was isolated from 100 g of Ehrlich ascites cells, and a tumour-specific tRNA^{Phe} which had chromatographic behaviour identical to that of tumour-specific tRNA^{Phe} from Novikoff hepatoma was purified by the procedure described earlier. This preparation accepted

Fig. 5 Fluorograph of tRNA^{Phe} from *a*, normal rat liver and *b*, Novikoff hepatoma (0.2 A₂₆₀ unit). Purified tRNA^{Phe} was digested for 6 h at 37 °C with a reaction mixture containing 3 µg RNase A, 3 µg of snake venom phosphodiesterase, 2.4 µg of *E. coli* alkaline phosphatase, 0.01 M MgCl₂, 0.03 M bicine buffer (pH 8.0) in a final volume of 20 µl. After appropriate dilution, the enzymatic digests were subjected to periodate oxidation and reduction with ³H-KBH₄ to form the tritium-labelled nucleoside trialcohols. The tritium-labelled nucleoside derivatives were separated on cellulose thin layers in solvent A (Acetonitrile-4 N ammonia, 3.4:1, v/v) and solvent B (*n*-amyl alcohol-methylethylketone-acetonitrile-ethylacetate-water-formic acid, 4.2:1.5:2:1.5:0.18, v/v). The tritium-labelled compounds were detected on X-ray film by fluorography. The base composition was calculated as described by Randerath⁸. Abbreviations used: O₂Y-Wye, peroxywybutine; U', A', C', G', nucleoside trialcohols of uridine, adenosine, cytidine, and guanosine; m⁵U', m¹A', m⁵C', m²G', m₂²G', m⁷G', m¹G', nucleoside trialcohols of 5-methyluridine, 1-methyladenosine, 5-methylcytidine, 2-methylguanosine, 2,2-dimethylguanosine, 7-methylguanosine, and 1-methylguanosine; hU', Ψ', nucleoside trialcohols of dihydrouridine and pseudouridine; gly, glycerol; Ψ-D, Ψ-M, decomposition products derived from pseudouridine.

Fig. 6 Fluorograph of tRNA^{Phe} from *a*, normal mouse liver and *b*, Ehrlich ascites cells. The method and abbreviations are as used for Fig. 5.

1.48 nmol of phenylalanine per A_{260} unit of tRNA, indicating 89% purity.

Nucleoside composition of tRNA^{Phe} from tumour and normal tissues

Figures 5 and 6 show the nucleoside composition, determined by the method of Randerath⁸, of tRNA^{Phe} from normal rat liver (Fig. 5a), Novikoff hepatoma (Fig. 5b), normal mouse liver (Fig. 6a) and from Ehrlich ascites cells (Fig. 6b). The unique presence of 1-methyl guanosine in tRNA^{Phe} from both malignant tissues is noteworthy. This modification is also absent from tRNA^{Phe} from two other mammalian sources (Table 1).

Table 1 gives the molar ratios of the major and modified nucleosides to tRNA^{Phe} from four different normal mammalian sources and from the two malignant tissues. Two modified nucleosides, dihydrouridine and 5-methyl cytosine were found to be elevated by 1 mol in the tRNA^{Phe} from the malignant tissues; otherwise, the composition coincides to within experimental error with that of tRNA^{Phe} from other mammalian sources. The total number of nucleosides in tRNA^{Phe} from Novikoff hepatoma seems to be higher than in those from other sources. Whether this augmented structure is real will be resolved by sequence analysis which is under way.

Discussion

The findings reported here provide unequivocal evidence for aberrant modification of a tumour-specific tRNA, but this does not rule out the possibility of altered nucleoside sequence as well. The paucity of the supernumerary methylated bases is at first glance surprising, in view of the very high activity of the tRNA methyltransferases in malignant tumour tissues. Studies in our laboratory, however, have demonstrated a very high turnover rate of tRNAs of tumour tissue¹⁰. Whether excessively methylated tRNAs are rapidly eliminated remains to be determined.

Given the numerous and varied roles of minor species of tRNAs in other systems, it is difficult to predict what, if any, aberrant attributes these minor changes in modification may confer on the tumour cell. Ames *et al.* have shown that the lack of modification of two Us to ψ's in tRNA^{His} makes a profound impact on the economy of *Salmonella*. In the absence of the modification of tRNA^{His},

a mutant *Salmonella* is continuously derepressed for the production of nine enzymes in the histidine-synthesising pathway, even in the presence of an adequate supply of histidine¹¹. The consequent waste in energy and material for the cell is enormous.

A more recent implication of a role of methylation of tRNA for transcriptional control has been adduced by Freundlich and his coworkers¹², who found that if a methionine auxotroph of *S. typhimurium* was deprived of its essential amino acid, there were changes in the chromatographic profiles of tRNA^{Val}, tRNA^{Isoleu} and tRNA^{Leu}. Incomplete modifications by methylation were evidenced by the ability of the total population of tRNAs to serve as substrate for methylation by homologous enzymes. Concomitant to the changes in the tRNA elution profiles there was a 5–10-fold increase in the synthetic enzymes for isoleucine and valine even though an excess of these amino acids was available to the organisms.

The evidence for the loss of functional effectiveness in derepression by undermodified tRNAs is, at present, circumstantial. Perfection of appropriate systems of tRNA-dependent transcription is needed for unequivocal evidence for loss of regulatory capacity by undermodified tRNAs.

What functional capacity is endowed—or deprived—by aberrant modification of tRNA in tumour tissue is not known. As the reality of aberrant modification has now been established, however, a search for altered functions of such purified tRNAs can be undertaken with confidence.

We thank Dr B. A. Roe of Kent State University, Ohio, for instruction in the method of base analysis. The work was supported by a grant CA 14047 from the US NIH.

α -Helix-double helix interaction shown in the structure of a protamine-transfer RNA complex and a nucleoprotamine model

R. Wade Warrant & Sung-Hou Kim

Department of Biochemistry, Duke University Medical Center, Durham, North Carolina 27710

Single crystal X-ray diffraction and circular dichroism studies of protamine binding to a tRNA suggest that the protamine molecule changes its conformation from a random coil to a structure containing a helices on binding to tRNA, and that α -helical segment(s) of protamine bind approximately along a shallow groove of a double-helical portion of tRNA. Based on these observations, a structural model for nucleoprotamine is proposed.

PROTAMINES are extremely basic, small proteins of molecular weights of about 4,200. They are found tightly associated with DNAs in fish spermatozoa. Nearly two-thirds of the amino acid residues in protamines are basic, and these basic residues are usually found clustered, four or five in a sequence. When protamine messenger RNA (mRNA) reaches the cytoplasm, the residues are translated by diribosomes. The newly synthesised protamines are phosphorylated by ATP in cytoplasm,

catalysed by protamine kinase on serine residues. The phosphorylated protamines are transferred into the cell nucleus and then into chromatin, where they replace the histones and bind to DNA. During the maturation of the sperm heads, the protamine is dephosphorylated, the DNA becomes more condensed, and all transcription stops.

Much research has been directed to find the mode of binding between protamine and double-helical DNA by X-ray diffraction methods¹⁻³, spectroscopic techniques^{4,5}, electron microscopy⁶ and chemical modification⁷. The most widely accepted view at present is that protamine exists in an extended chain which wraps around double-helical DNA, covering the narrow groove along the DNA double helix^{1,2}, or sometimes crossing over to a neighbouring DNA double helix^{6,8}, with the positively charged basic side chains of protamine neutralising negatively charged phosphates of the polynucleotide chain. In a less specific model⁹, hexagonally arranged parallel rods of double-helical DNA are held together loosely by a network of protamines.

Fig. 1 Packing diagram of yeast phenylalanine tRNA in an orthorhombic crystalline form (P_{2121}) viewed along the crystallographic axis a . Two L-shaped tRNA molecules at an angle are shown shaded, and two types of channels are indicated. The large channels (a) have a diameter of > 40 Å, and the small channels (b) have a diameter of approximately 15 Å. This figure represents the thickness of the unit cell along the a axis. In the crystal, this packing is repeated indefinitely in all three directions, all exactly registered. In this crystalline form, the volume occupied by tRNA is approximately 25%, and that for the buffer is approximately 75%.

To understand the interactions between protamines and nucleic acids in more detail, we investigated crystallographically the interactions between protamines and transfer RNA (tRNA) primarily because tRNA has been crystallised in several suitable single crystalline forms, whereas DNA has not.

Yeast phenylalanine tRNA crystallises into an orthorhombic lattice, in which 75% of the total volume is occupied by buffer solution. There are two kinds of channels in this crystal form (Fig. 1). The large channel, *a*, is over 40 Å in diameter and the small channel, *b*, is about 15 Å in diameter. Thus, this crystal form provides an open crystalline matrix into which various molecules can be soaked, to study their interaction with tRNA by single crystal X-ray diffraction techniques. Since a large portion of tRNA structure is double helical, this system can be considered for studies involving double-helical RNA in general. We report here the crystal structure of a protamine-tRNA complex at 5.4 Å resolution. Based on the information obtained from the structure and model building, a structural model for nucleoprotamine is proposed.

Materials and methods

Single crystals of transfer RNA were grown in a buffer containing 40 mM MgCl₂, 40 mM Na cacodylate, 3 mM spermine hydrochloride at pH 6.0 (ref. 10). Yeast phenylalanine tRNA was purchased from Boehringer-Mannheim, and protamine sulphate from salmon sperm was purchased from Sigma. Protamine sulphate was dissolved in the same buffer solution as the tRNA crystallisation buffer, and then added to a small depression containing tRNA crystals to yield a protamine-tRNA molar ratio of 4:1. After several days, the soaked crystals were sealed in glass capillaries and X-ray data were collected on an automatic four-circle diffractometer.

The sizes of crystals used for collection of X-ray data were about 100 × 150 × 500 μm. The soaked crystals had the same space group symmetry, and the cell dimensions changed less than 0.4%. Five steps per reflection were measured and individually fitted to a Gaussian curve to estimate integrated intensities for each reflection. A total of 1,253 reflections was collected up to 5.4 Å resolution, and of these, 1,011 had intensities significantly (greater than 4σ: where σ is an estimated standard deviation of each intensity) above the background. This data set was scaled to that obtained from a native tRNA crystal (which did not contain any protamine) as a function of resolution. The discrepancy factor (*R* factor) between these two data sets was 8% for the structure factor amplitudes. A difference electron density map was prepared, using the differences of amplitudes between these two data sets and the phases calculated from the atomic coordinates of the yeast tRNA^{Phe} structure in an orthorhombic lattice. The three-dimensional structure of this tRNA has been determined¹¹ and refined by a structure factor least-squares method¹².

Eleven residues from the C terminus of a salmon sperm protamine, Salmine A1, were folded to generate an α helix and then fitted to the difference electron density map obtained as described above, using an interactive computer graphics system at the University of North Carolina, Chapel Hill. After a portion of the α helix was fitted approximately into the electron density, it was further refined by treating the α helix as a rigid body. Three rotational and three translational parameters, as well as the occupancy and the overall temperature factor, of the α helix were refined by minimising the difference between calculated structure factors and the observed structure factors using a least-squares method¹³.

Circular dichroism (CD) measurements were made on a Dichrographe III of Jobin-Yvon using a quartz cell with path-length of 1 mm. The stock solutions for the CD measurements were: a buffer solution containing 10 mM MgCl₂, 10 mM Na cacodylate and 1 mM spermine·4HCl at pH 6.0; a tRNA solution containing 5.3 mg ml⁻¹ of yeast tRNA^{Phe} in the buffer described above; the protamine solution containing 12.5 mg ml⁻¹ salmon protamine sulphate in the same buffer. CD profiles were recorded for each of these solutions, and for

mixtures with protamine-tRNA molar ratios ranging from 0:1 to 16:1.

Structure of a protamine-tRNA complex

The results of the CD measurements are shown in Fig. 2. As protamine was added to the tRNA solution, we observed an increase of precipitation, and a decrease of tRNA in solution, indicated by the reduction in the magnitude of θ while the curve shape remained the same. When the molar ratio of protamine to tRNA reached 4:1, practically all tRNA and protamine in the solution was precipitated (Fig. 2*f*). This molar ratio corresponds to a stoichiometry of 1.1 positive charges of protamine per 1 negative charge of tRNA, if one assumes that salmon sperm protamine A1 is representative of all salmon sperm protamines. At present, this is the only protamine from salmon sperm that has been sequenced¹³, and it contains 32 residues of amino acids of the following sequence:

```
PRO ARG ARG ARG ARG SER SER ARG
PRO VAL ARG ARG ARG ARG ARG PRO
ARG VAL SER ARG ARG ARG ARG ARG
ARG GLY GLY ARG ARG ARG ARG
```

Fig. 2 Circular dichroism spectra of complex formation between salmon sperm protamine and yeast phenylalanine tRNA. The molar ellipticity θ is on one axis and the wavelength (nm) on the other. The θ value of curve *b* at 265 nm is 1.895×10^3 degrees cm² dmol⁻¹. The measurements were made for the wavelengths between 300 nm and 205 nm. *a*, A buffer solution containing 10 mM MgCl₂, 10 mM Na cacodylate and 1 mM spermine·4HCl with pH adjusted to 6.0; *b*, tRNA solution containing 1.0 mg ml⁻¹ of yeast tRNA^{Phe} in the buffer solution described above; *c*, the protamine solution containing 4.0 mg ml⁻¹ salmon protamine sulphate in the same buffer; *d*, 12.5 mg ml⁻¹ protamine stock solution was added to the tRNA solution described for *b* to give a molar ratio of protamine-tRNA of 0.25:1; *e*, molar ratio of 1:1; *f*, molar ratio of 4:1; *g*, molar ratio of 16:1.

The difference electron density map revealed only one kind of long, partially segmented electron density peak, running zig-zag along the small channel (channel *b* in Fig. 1) formed by tRNA molecules in crystalline lattice as shown in Fig. 3. This was the only peak present when contoured at the level of 5σ where σ represents root mean square electron densities in the difference electron density map. There were no significant negative peaks either. Each electron density segment is approximately cylindrical and corresponds in size to an α helix of about nine or ten amino acids (see Fig. 3*C*). Each segment is in contact, on a shallow (minor) groove side, with both strands of one double helix from a tRNA molecule (see Fig. 4) and one strand each of two other double helices from a neighbouring tRNA molecule.

When the α-helical portion of the structure was refined by a least-squares method, the occupancy and the thermal parameter were 20% and 90 Å² respectively. Since the asymmetric portion of the electron density can accommodate only about nine or ten of 32 amino acid residues, we assume that a part or all of the protamine molecule is partially disordered along the chain of electron density and that the kinking of the electron densities probably represents the kinking of the α helix at sites prior to

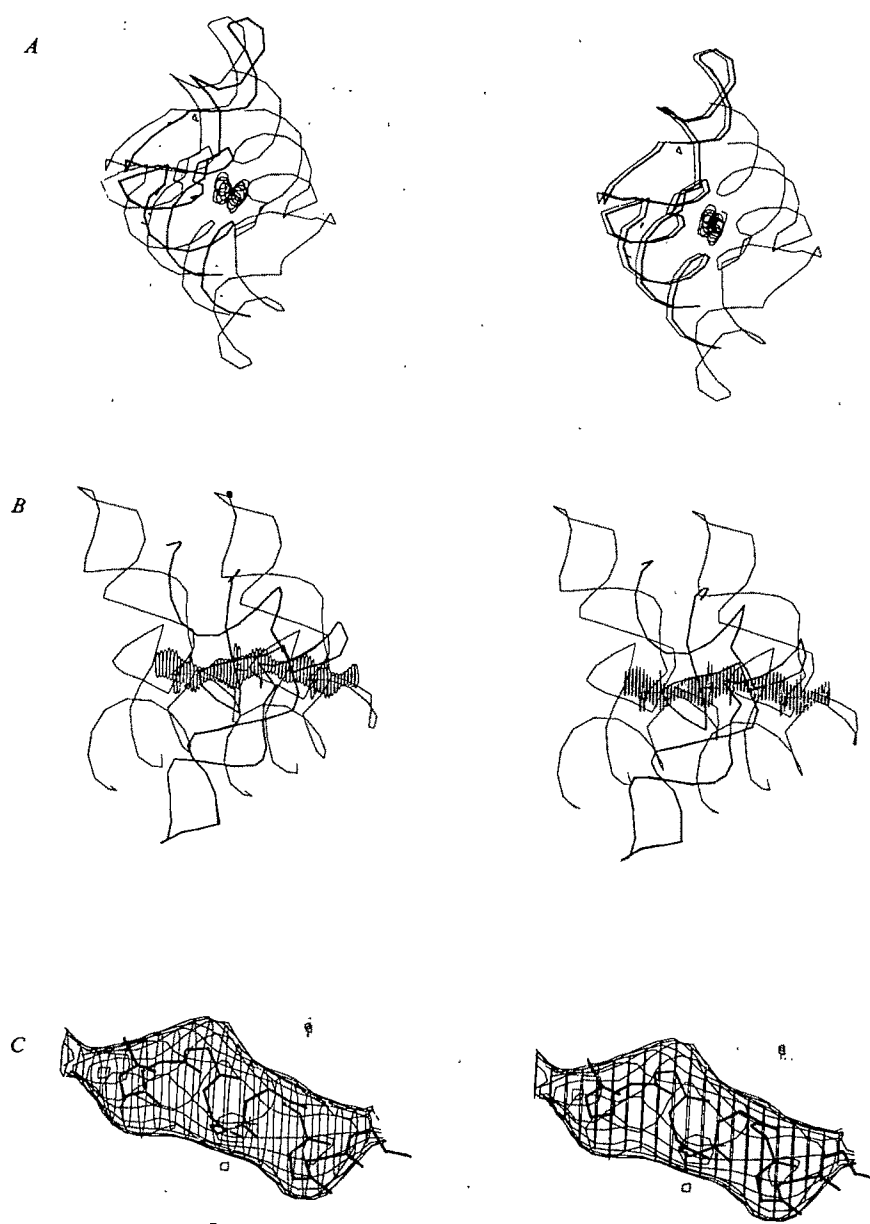

Fig. 3 The difference electron density map between the crystal of protamine-yeast tRNA1/1 and the native crystal of yeast tRNA1/1. The contouring level was chosen to show, primarily, the major feature of the difference electron density. The backbone structure of the tRNA is superimposed to show the relative position of the electron density peaks in the crystalline lattice. *A*, viewed approximately along the crystallographic axis *a* (for clarity, only two cylindrical segments are shown). *B*, Three cylindrical segments, viewed along the crystallographic axis *b*. The channels are running approximately along the crystallographic axis *a*. *C*, The fitting of a unique asymmetric portion of the difference electron density map with an α -helix ten residues long.

two internal prolines and a pair of glycines in the amino acid sequence (see Fig. 5 and below).

Conclusions and discussions

On the basis of our results from single crystal X-ray diffraction and CD studies, we make the following conclusions.

The protamine molecule changes its conformation from a random coil structure to a structure containing one or more α -helical segments in the presence of tRNA and possibly other nucleic acids. This is based on the observation that protamine in solution, in the absence of tRNA, gives a CD spectrum typical of a mostly random coil (see curve *c* of Fig. 2). This observation is consistent with the earlier observations from deuterium exchange and spectroscopic experiments^{4,14}. In the presence of tRNA, however, the protamine forms a complex with tRNA and precipitates. The crystal structure of the protamine-tRNA complex suggest that at least a portion of the protamine which is in contact with tRNA is in an α -helical conformation.

In a protamine-tRNA complex, the stoichiometry of positive charges of protamine to negative charges of tRNA is approximately 1:1. This is based on the observation from the CD study which shows that when the molar ratio of protamine to tRNA is 4:1, all the tRNA and protamine have been complexed and precipitated and no appreciable tRNA or protamine remains in

solution. At such a molar ratio, the stoichiometry between positive charge from protamine and negative charges from tRNA is approximately 1 to 1. This charge stoichiometry is the same as that observed for protamine-DNA complexes (for review, see ref. 8).

The protamine molecule binds to tRNA nonspecifically. As mentioned earlier, the yeast phenylalanine tRNA in the orthorhombic crystal form occupies only 25% of the crystal volume, with the remainder being buffer solution. tRNA molecules in this crystal form make a small number of contacts which barely maintain the crystalline lattice, thus most of the molecular surface of tRNA is exposed to buffer solution and should therefore be available for protamine binding. In fact, the absorbance measurement at 202 nm of the mother liquor in equilibrium with tRNA crystals showed that more than 99.3% of the protamine added was bound in the tRNA crystals. The difference electron density map, however, shows that the significant peaks are found only in the small channel *b* of Fig. 1. Since the single crystal X-ray diffraction studies can reveal only the ordered or partially ordered portion of the protamine structure, this crystallographic observation can be interpreted as follows: The protamine binds to all available parts of tRNA. But they bind with no site specificity and, therefore, they are not ordered or partially ordered in a crystalline lattice. In channel *b*, however, which is relatively narrow and restricted spatially by

the tRNA molecules nearby, the protamine molecules probably have much less freedom in binding and thus are partially ordered, and therefore 'visible' by single crystal X-ray diffraction techniques.

Protamine molecules, or the α -helical portion of protamine molecules, can stabilise not only an individual double helix, but also two or three adjacent double helices, thus helping the close packaging of double-helical RNA and possible DNA. This is based on the following observations: at a 4:1 molar ratio of protamine-tRNA, protamine helps to aggregate and precipitate tRNAs; in the crystal, the α -helical portion of protamine is sandwiched between a double-helical portion of tRNA from one molecule and one strand each from two more double-helical portions of a neighbouring tRNA molecule (Fig. 3A). Within this contact region, the distance between the α helix of the protamine segment and the phosphate groups of tRNA suggests that the guanidinium groups of extended arginine side chains can hydrogen bond to and, at the same time, neutralise, the negative charges of phosphates of tRNA. In the crystal, the α -helical segment was seen to bind to the shallow (minor) groove but not to the deep groove of the double helical portions of tRNA (Fig. 4), probably because only the shallow grooves of the T stem and acceptor stem are exposed to channel B.

From these conclusions, some general comments may be made about the possible mode of interaction between protamine and double-helical RNA or DNA. Given that protamine changes its conformation from a random coil to an α -helical structure in the presence of double-helical RNA or DNA, then Salmine AI protamine can be described, for example, as a structure with four segments of α helices with an average of about eight residues each, joined by three partially flexible joints, as shown schematically in Fig. 5. These joints are at residues 9, 16 and 26, all followed by well known helix-breaking residues, proline and glycine¹⁵. This prediction also follows from the consideration that, since each segment contains similar amino acids, if one segment assumes α -helical conformation in certain conditions, the others are also likely to assume the same conformations in the same condition, yielding four α -helical segments.

Nucleoprotamine model

The amino acid sequences of several fish sperm protamines have been determined (for a convenient compilation, see ref. 16). All of these sequences have the following aspects in common (see Fig. 6): they are 31–34 residues long; each begins with proline or alanine, followed by eight to ten residues, of which all except three are basic; and then another proline residue followed by five or six residues, all except one being basic; then another proline or tyrosine, followed by 13–17 residues,

Fig. 4 Schematic drawing showing the location of an α -helical segment bound to the shallow groove of the T stem of yeast phenylalanine tRNA. The α -helical segment is shown as a cylinder. The shallow grooves in the tRNA structure are shaded.

Fig. 5 Diagrammatic representation of Salmine AI protamine structure. This protamine is assumed to be composed of four α -helical segments joined by three partially flexible joints at residues just prior to two internal prolines and one joint before a pair of glycine residues. Arginines are shown as dark circles; and P and G stand for proline and glycine respectively.

all except three to six being basic amino acids. Thus, one can consider the general structure of protamine as composed of at least three segments, with two middle joints being a proline, tyrosine, or alanine residue. Even the last segment can be subdivided, in most cases, into two with a joint before a pair of glycines or valines.

Based on the observations from the crystal structure of the protamine-tRNA complex described here, we propose that all protamines have a structure composed of three or four α -helical domains connected by two or three flexible joints as suggested in Fig. 6 and shown schematically in Fig. 5 for Salmine AI protamine. Each α -helical domain contains four or more consecutive arginine residues, and can lie approximately along either groove of double-helical DNA. Two arginines facing the groove can neutralise and hydrogen bond to two negatively charged phosphates across a groove of one double helix. At the same time, the remaining arginines in the same α -helical domain can hydrogen bond to and neutralise the negatively charged phosphates of the neighbouring double helices, thus 'condensing' many double helical DNAs.

Although the backbone of an α helix does not have a structural complementarity to double-stranded nucleic acids as was noted for a β ribbon¹⁷, two nearby residues with long side chains like arginine and lysine in an α helix can place both basic groups about 10 Å–16 Å apart, depending on the side-chain conformation, just suitable to span across either groove of a double-stranded DNA or RNA.

A schematic drawing of the nucleoprotamine model is shown in Fig. 7 and described below. Model building suggests that the α -helical domains are more likely to lie on the major groove of double-helical DNA, although the minor groove cannot be ruled out. Two (or three when the arginine tract is longer than four) arginines of each domain neutralise and hydrogen bond to two (or three) phosphates across a major groove and the remaining arginines do the same to the phosphates of neighbouring double helix or helices. Each domain is thus binding or 'cross-linking' two or more double helices together, thereby causing a heavy condensation of DNA double helices.

Since the protamine α helices lie mostly on the major groove in this model, it is consistent with the observation in X-ray diffraction pattern of nucleoprotamine fibres, where the first layer-line intensities are stronger compared with the second layer-line^{1,2}. The di- or trivalent binding property of the α -helical segments of protamine can explain the electron microscopic observation on reconstituted nucleoprotamine⁶, where double-helical DNAs were shown to form a network. This also explains the observation that nucleoprotamine fibres do not swell as much as DNA on exposure to high humidity¹. Such cross-linking ability is likely to stabilise superhelical structure of DNA also. Although α -helical domains of protamine lie on the major groove of DNA double helix, the surface of the groove is essentially exposed to the solvent, because of the large spacing between the axis of the α helix and the groove surface caused by the long reach of arginine side chains (shown

Fig. 6 All the known sequences of protamines¹⁶ are arranged to show four proposed domains. Abbreviations: A, alanine; E, glutamic acid; G, glycine; I, isoleucine; P, proline; Q, glutamine; S, serine; T, threonine; V, valine; Y, tyrosine; +, arginine.

schematically in the inset of Fig. 7). This aspect of the model is consistent with the results that dimethyl sulphate can methylate the N-7 atom of guanine in the major groove and the N-3 atom of adenine in the minor groove of the DNA double helix with equal relative efficiency but with small retardation on the major groove side⁷ at low temperature.

Functional implications of the model

The protamine structure proposed here has several advantages as a DNA-condensing agent: The α -helical domains have structural rigidity and just sufficient length to stabilise DNA double helix-double helix cross-linking or 'condensation'; also, the joints between the α -helical domains provide flexibility in the orientation of the domains, so that two DNA double helices in variety of orientation can be brought together. Such extensive DNA condensation is probably the major reason for the inhibition of DNA-dependent RNA synthesis by protamines¹⁸.

The newly synthesised protamines are usually phosphorylated at serine residues¹⁹. The model proposed here suggests that such modification on protamines will interfere with the cross-linking of two adjacent DNA double helices. The following sequence of events can be imagined: The phosphorylation of protamines is probably necessary so that the modified protamines can efficiently displace histones and prevent DNA condensation (which will complicate the process). Once histone displacement is almost complete, dephosphorylation starts and so does the concomitant DNA condensation as a necessary step in the sperm maturation process.

The proposed model can explain several experimental observations and suggests some functional implications; however, the reason for the existence of multiple components in a protamine is not obvious from the model. It is likely that the similar interaction between two well defined structural elements, the α helix of protein and double helix of nucleic acids, may be found in other complexes between proteins and double-helical nucleic acids, such as in nucleosomes.

We thank Yasuhiko Nozaki, John Boyle, Joel Sussman, Steve Holbrook, and Charles Alden for help and discussions. This work was supported by grants from the National Institutes of Health and the National Science Foundation. The model fitting and some of the drawings were done with the aid of the GRIP-75 molecular graphics system, built by the University of North Carolina Department of Computer Science. Major system contributions were made by E. G. Britton, J. S. Lipscomb, M. E. Pique, W. Siddall, J. E. McQueen Jr,

Fig. 7 Schematic drawing to show parts of nucleoprotamine structure. Protamine molecules are represented by several connected cylinders; each corresponds to an α -helical segment. They wrap around the major groove (shaded) of the DNA double helix shown as a long large cylinder. Inset, an α -helical segment with four consecutive arginine residues (represented as four rods radiating out from the cylinder) is shown in two-orthogonal orientations. Two types of possible cross-linking are shown. Between the left and middle DNA double helices, there are two α -helical segments with arginine side chains shown as straight lines. Each segment forms two contacts across a major groove of one DNA double helix and two across a minor groove of the other DNA double helix. Between the middle and the right DNA double helices, three α -helical segments from one protamine molecule are in contact on the major groove of the middle DNA double helix and the fourth segment on the major groove of the right DNA double helix. There are many other types of cross-linking possible.

X-ray lines and magnetic field of Her X-1

THE report¹ of a possible detection of an X-ray emission line with energy about 53 keV from the binary X-ray source Her X-1 created great excitement. Interpreting the line as arising from non-relativistic electron cyclotron emission at the surface of an accreting neutron star member of the binary star system, Trumper *et al.*¹ deduce a neutron star surface magnetic field of 4.6×10^{12} G. If the line is real (of cosmic origin and not due to background effects), significant (not due to a statistical fluctuation) and correctly interpreted as arising from non-relativistic cyclotron emission) it could provide the first direct and quantitative measure of the magnetic field of a neutron star, and be direct support for our ideas on the formation of neutron stars and the role of magnetic fields in the radiation mechanisms of pulsars and binary X-ray sources. Furthermore, it would conclusively rule out the possibility that Her X-1 contains a rotating or pulsating white dwarf (which, for dynamical stability requires $B \leq G^{1/2} M R^{-2} \approx 10^{12}$ G for $M \approx M_{\odot}$ and $R = R_{WD} \approx 10^9$ cm).

Coe *et al.*² reported the detection of a line at 64 ± 6 keV in the Her X-1 X-ray spectrum from observations made with the Ariel 5 satellite. The energy of their line is consistent, within observational uncertainties, with the line energy reported by Trumper *et al.*¹ (53 ± 8 keV). In light of these two reports, we have re-examined the UCSD OSO-7 observations³ of Her X-1 made in 1971 and 1972. As can be seen in Fig. 1, these data from May to June 1972 contain a large deviation from the blackbody best fit at about 25 keV. This feature seems to be about as significant (or insignificant) as that reported by Coe *et al.*² No X-ray flux was detected at energies above about 50 keV for this source. The > 50 keV data were, therefore, combined to form the upper limit shown in Fig. 1. As can be seen, the best fit continuum falls steeply and we could set no meaningful upper limit to a 60 keV line.

The observations of Her X-1 were made with the UCSD OSO-7 NaI (TI) 64 cm² 1 cm thick actively collimated detector. The spin rate of the satellite was 2 s per rev. This allowed continuous measurements of both the X-ray source and detector plus sky background^{3,4}. The 29 May to 1 June Her X-1 spectrum derived shows a feature at about 25 keV. If this feature were due to a line from Her X-1 itself, we estimate the intensity of the line as $2.4 \pm 1.2 \times 10^{-2}$ photons cm⁻² s⁻¹ centred at about 25 keV. A cosmic X-ray line would produce a deviation in at least one other energy channel (since one channel is about 4 keV wide), and by a judicious choice of continuum, a cosmic X-ray line is consistent with the data. But, there are alternative interpretations of such a feature. We discuss the two most likely ones below.

The UCSD OSO-7 instrument was subjected to bombardment by many low energy protons and neutrons during its passages

through the South Atlantic Anomaly. As a result, several features were present in the detector background, including an apparent line at about 30 keV, as well as a line at about 60 keV as shown in Fig. 2. These features are due to conversion of the iodine in the NaI (TI) crystal to radioactive nuclei. Effects such as this have been discussed extensively^{5–9}. In the UCSD OSO-7 experiment, the detector background 25 keV feature is comparable in intensity to the derived 25 keV flux from Her X-1. We tried to eliminate the feature from the Her X-1 data by using only the results taken a long time after the last South Atlantic Anomaly passage of the satellite. The feature remains as shown in Fig. 1. We estimate that an error in the background subtraction could have caused no more than a 10% error in the derived 25 keV flux from Her X-1. The one outstanding feature, however, in the OSO-7 Her X-1 data occurs at just the energy of one of the X-ray detector's background lines.

Trumper *et al.*¹ do not report a line at ~ 25 keV. If the OSO-7 Her X-1 feature were cosmic in origin, it might be variable, or Trumper *et al.* and Coe *et al.* might not have had the sensitivity to

Fig. 1 Average spectrum of Her X-1 from the UCSD OSO-7 cosmic X-ray detector³. Observations from 29 May–1 June 1972. The solid line fit is a minimum blackbody fit giving $T = 5.6 \times 10^7$ K.

Fig. 2 Energy deposition spectrum for the UCSD OSO-7 cosmic X-ray detector. The solid line is derived from Earth-looking portions of the satellite orbit. The dashed line is derived from sky looking data excluding strong cosmic X-ray sources⁸.

an X-ray line of the OSO-7 instrument near 25 keV. The lowest energy that the Coe *et al.*² instrument could detect is about 25 keV, which might not have been low enough to be relevant to this report.

Another explanation that cannot be excluded is that the 25 keV Her X-1 feature is simply a statistical fluctuation. This is because: (1) the data point is only about 2σ above the continuum flux and (2) *a priori*, we do not know where to expect the line, and therefore finding a line in any one of five channels is five times as likely as deduced on the basis of simple Poisson statistics. This makes the present 'detection' only about 1.5σ . But, the same factor applied to the results of Trümper *et al.*¹ for example, also reduces the significance of the results from their two detectors from 6.2 and 4σ to about 5σ and 3σ respectively.

Adding the statistical uncertainty to the possibility of background contamination, it is unlikely that the UCSD OSO-7 keV feature in the Her X-1 spectrum is of cosmic origin. On the other hand, we cannot exclude such a possibility. We shall therefore briefly discuss the consequences of assuming the line is real and arises from cyclotron emission from Her X-1.

Even if one or all of the line features discussed above are of cosmic origin and arise from cyclotron radiation from electrons moving in the strong magnetic field of a neutron star, many uncertainties arise in trying to make a quantitative determination of the value of the B field. This is important because we already have rough arguments supporting the notion of 10^{12} – 10^{13} G magnetic fields at the surface of neutron stars (the value expected from collapse of a main sequence star of radius $R_0 = 10^{11}$ cm and surface magnetic field 100 G by conserving flux BR^2 to a neutron star of radius $R_n \approx 10^6$ cm). We summarise some of these estimates below⁹. (1) The naive theory of pulsar emission suggests that the pulsar energy loss rate is related to the pulsar radius R , magnetic field B , angular velocity Ω , spin down rate $\dot{\Omega}$ and moment of inertia I by

$$dE/dt \approx I\Omega\dot{\Omega} \approx B^2 R^6 \Omega^4 f(R\Omega/c)/c^3$$

where $f(R\Omega/c)$ is a dimensionless number, probably of order 1. From the observed values of dE/dt for the Crab Pulsar NP0532 and of Ω and $\dot{\Omega}$ for other pulsars one finds $B \approx 10^{12}$ – 10^{13} G. (2) Accretion models of binary X-ray sources such as Her X-1 suggest $B \approx 10^{12}$ to 10^{13} G and require $B > 10^{10}$ G in order for the Alfvén radius to be greater than the stellar radius. (3) Finally, for

dynamical stability of the neutron star, one requires $B \ll 10^{17}$ G.

Many factors play a part in making a quantitative derivation of the magnetic field strength from the observation of the X-ray line. For example, if one assumes that the field has a magnetic dipole configuration, the emission must arise¹ from a region with $\Delta B/B < 0.3$ so that the line is not broadened too greatly, in which case one has $\Delta r/r < 0.1$. Emission arises then from a region within 1 km of the neutron star surface. Second, the emitting region must be optically thin, so that the line is not broadened, shifted and smeared beyond recognition. The detailed radiative transfer in this region is not known, various theoretical models of such effects notwithstanding^{11–13}. Next, a line emitted from the surface of a neutron star must be corrected for redshift¹⁴ which can range from ~ 0 to as much as ~ 0.6 . (This depends on the mass of the star, its equation of state, and the theory of gravity used. For incompressible matter in general relativity, however, $z_{\max} = 2$.) Fourth, if the magnetic field is of order 10^{12} G or greater, the classical electron cyclotron radiation energy will be $\Delta E = \hbar\omega = (e\hbar/mc)B$ for electrons of $v/c \ll 1$. But for $B \approx 10^{12}$ G, $\Delta E \sim 50$ keV, the energy is not negligible compared to the electron rest mass energy. Looked at another way², as the de Broglie wavelength for a 50 keV electron is greater than its cyclotron radius, a relativistic quantum mechanical treatment of the problem is necessary. For electrons with momentum p_{\parallel} parallel to the field, spin state s and principle quantum number n , the energy levels found as eigenvalue solutions to the Dirac equation are given by

$$E = \pm [c^2 p_{\parallel}^2 + m_0^2 c^4 + e\hbar c B(2n + s + 1)]^{1/2}$$

Thus depending on what spin or principle quantum numbers are chosen, the deduced magnetic field will differ from that derived using a non-relativistic (classical or quantum) treatment. For example, if one considers only n states (with $s = -1$, say) the relativistic and non-relativistic treatments can give results differing by a factor of ~ 2 . If one takes all of these effects into account, the deduced field strength can vary from 10^{12} G (for a neutron star of mass $M \approx 0.6M_{\odot}$, lowest energy level or first harmonic at 25 keV) to about 10^{13} G (for a neutron star of $2M_{\odot}$ and taking the first harmonic as the 64 keV line). It is comforting that this range covers the field range deduced from other arguments. A more precise result would require much more detailed information about the neutron star itself, the accretion rate, the topology of the B field, temperature of the radiating electrons, and a host of other parameters.

Observations in the near future from HEAO 1 should be able to establish the reality, energy pulse fraction and relative strength of one or both of the X-ray line features we discussed here. Perhaps detection of linear or circular polarisation in the lines could test the cyclotron origin. The discovery of lines at similar (but not exactly the same) energy might be expected from other X-ray binary systems containing accreting neutron stars.

Radioastronomical frequency for interstellar NH^+

SOME spectroscopic frequencies may be calculated more accurately than laboratory experiments can measure them. *Ab initio* molecular orbital calculations can be used to compute molecular properties, but none as accurately as Λ -doubling. This effect gives rise to splittings of molecular energy levels of diatomic molecules and transitions between the Λ -doublets are the sources of some of the most important radioastronomical spectral lines. Here we consider the as yet unobserved but very likely instellar species NH^+ .

Very crudely, Λ -doubling may be thought of as an effect of electron slip as the molecule rotates; the electrons lagging somewhat behind the rotating nuclear frame. This results in the energies of degenerate Π molecular energy levels becoming different, with an energy separation which increases as the rotational quantum number increases. Formally the effect may be described as the influence of Σ electronic states on Π states. The interaction, which is zero to a first approximation, is dominated by spin-orbit coupling, giving non-zero matrix elements between Σ and Π states.

The well-known astrophysical source, OH, was the subject of calculations¹ which would now be thought of as relatively crude, but in wave numbers the agreement with experiment is impressive (observed 0.0788 cm^{-1} ; calculated 0.0810 cm^{-1}). This encouraging result was, in a sense, fortuitous because the origin of the splitting in OH is particularly simple, being an example of Van Vleck's approximation of pure precession where the $^2\Pi$ electronic ground state is only seriously influenced by a single $^2\Sigma^+$ state.

The case of CH is more complex as several states of $^2\Sigma^+$ and $^2\Sigma^-$ symmetry have to be considered, but agreement with experiment³⁻⁵ is close enough for the computations to be within a few MHz of the observed astrophysical frequency.

We have now extended this work to the species, NH^+ , where a further complication enters the calculations. In this case we have to consider not only interacting $^2\Sigma^+$ states but also $^4\Sigma^-$ states. Configuration interaction wave functions and potential energy curves were calculated for the $X^2\Pi$, $a^4\Sigma^-$, $A^2\Sigma^-$ and $C^2\Sigma^+$ states of NH^+ using the Alchemy system of computer programs⁶. Using these wave functions and potential energy curves the interaction between the $X^2\Pi$ state and the $a^4\Sigma^-$ state was treated numerically, whilst the interaction with the $^2\Sigma^+$ states was calculated using second-order perturbation theory. It is important that because of the influence of the $^4\Sigma^-$ state, the Λ -doubling in the $X^2\Pi$ state of NH^+ cannot be interpreted in terms of the conventional constants p and q and each rotational level must be treated separately.

The results of these calculations predict Λ -doubling in the lowest rotational level of $^{14}\text{NH}^+$ to be 13.625 MHz. This may be compared with the best laboratory experimental value of $13.520 \pm 300\text{ MHz}$ for which special measurements were made⁷.

The splittings to be expected in $^{14}\text{ND}^+$ and $^{15}\text{NH}^+$ together with values in excited rotational levels for which accurate experimental measurements are not available will be published elsewhere with fuller details of this work.

Our predicted frequency of NH^+ is within the range of available radiotelescopes and the calculations could provide the first example of a case where theory has predicted a radio source rather than merely confirmed its identification.

The computational work has been supported by a grant from the SRC and forms part of a project supported by a NATO research grant.

Irreversibilities in the mechanism of photoelectrolysis

PHOTODECOMPOSITION of water using semiconducting electrodes is being widely investigated. Using a combination of theoretical methods and experimental results we have analysed the sequential processes involved in this phenomenon and show here that several steps are irreversible. Some of the consequences of these irreversibilities are discussed. A theory of electronic charge transfer between electrodes and aqueous electrolytes, based on an equilibrium approximation by Marcus¹, seems to be valid for metal electrodes. Gerischer² has considered both metal and semiconductor electrodes and concluded that in general the electron is isoenergetically injected (tunnels) from the occupied band state of the electrode into an unoccupied state of the electrolyte. Rearrangement of the molecular environment then occurs, irreversibly changing the energy of the electronic state of the electrolyte. Finally, reverse tunnelling from the relaxed state back into the electrode may occur.

The two states of occupancy in the electrolyte constitute a redox couple. For metals the forward and reverse currents become equal as equilibration occurs; thus, the Fermi level of the metal adjusts to the redox potential of the redox couple of the electrolyte. For semiconductors, electronic charge transport involving different bands (electrons in the conduction band and positive holes in the valence band) have been separately considered³. This situation can lead to either an equilibrium or a non-equilibrium charge transfer process between semiconductors and electrolyte. The equilibrium approximation frequently appears in analyses of electronic charge transport between semiconductors and electrolytes. In particular, Gerischer³ has invoked the quasi-Fermi level concept to describe the charge carrier concentrations at the semiconductor-electrolyte interface under illumination.

Here we point out some irreversible aspects of charge transfer across semiconductor-electrolyte interfaces for photogenerated minority carriers, and emphasise the importance of these irreversibilities in explaining photoelectrolysis⁴⁻⁷ and the mechanism of the operation of the photochemical diode⁸. Furthermore, we believe that as a consequence of these irreversibilities, the quasi-Fermi level concept and the associated thermodynamic arguments are of limited validity for high efficiency photoelectrolysis. Irreversibility, has previously been proposed to explain reduction of ferricyanide at a ZnO semiconductor electrode⁹.

The energy level diagram for the n -type semiconductor electrode-aqueous electrolyte interface involved in photoelectrolysis is shown in Fig. 1. The essential features of the semiconductor-electrolyte junction are from Nozik¹⁰; the electronic states of water are from Williams *et al.*¹¹. The bending of the conduction and valence band edges, E_c and E_v respectively, are determined by the space charge arising

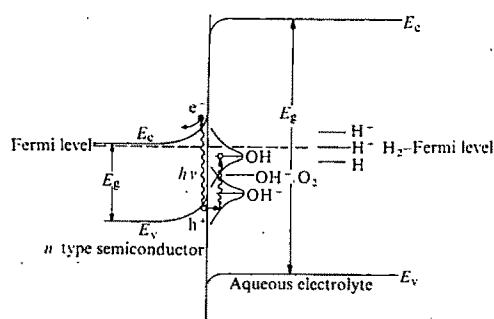

Fig. 1 Energy level diagram of *n*-type semiconductor (TiO_2 , $E_g = 3\text{eV}$) in contact with aqueous electrolyte ($E_g \approx 9\text{eV}$) showing energy bands of water and its extrinsic states. The energy levels of the extrinsic states have a distribution due to thermal fluctuations in the solvation structure; this is shown for the OH° and OH^- states.

from the difference in work functions of the semiconductor and of the electrolyte. The extrinsic states, H^+ and OH^- , are approximate, having been estimated from continuum theory¹¹. At the interface the macroscopic dielectric constant and the continuum approximation for small ions in solution are not strictly valid. The rearrangement energies can be similarly estimated, but for our purposes are taken from Henglein¹².

The sequence of events at the *n*-type semiconductor anode during photoelectrolysis are: (1) the incident quantum of radiation, $h\nu$, is absorbed in the semiconductor and thus creates a conduction electron and a valence band hole; (2) the electron, which is the majority carrier with energy very near the Fermi level, is displaced by the band bending into the external circuit, and the positive hole which is the minority carrier, and as such has energy available for radiative transitions or chemical changes, is displaced by the band bending towards the interface with the aqueous electrolyte; (3) the positive hole tunnels from the valence band edge into OH^- molecular ions at or near the interface; (4) a neutral OH° species is formed which causes the orientated H_2O molecules which surround the OH^- ion to relax, perturbing this extrinsic electronic state closer to the Fermi level; and finally (5) the chemistry to form O_2 proceeds according to the overall reaction: $4\text{OH}^\circ \rightarrow 2\text{H}_2\text{O} + \text{O}_2$.

Experimental data on the photoelectrolysis of water using *n*- TiO_2 anodes and Pt cathodes indicate that the quantum efficiency (that is, the fraction of absorbed photons producing charge carriers which are injected into the electrolyte to propagate the anode reaction) is high, especially if the band bending in the space charge region is reasonably large and the depletion width (w) is greater than the absorption depth ($1/\alpha$), where α is the absorption coefficient in cm^{-1} . Thus, for example, at 3,100 Å, where $\alpha = 6 \times 10^5 \text{ cm}^{-1}$ for TiO_2 , the quantum efficiency for the oxidation of water to O_2 at the TiO_2 anode is reported to be 1.0 (A.J.N. and R. R. Chance, unpublished and ref. 7). Under these conditions, the band bending is 0.9 eV (ref. 7), the absorption depth is 170 Å, and the depletion width is calculated to be 200 Å; the latter calculation is based on a carrier density of $2 \times 10^{19} \text{ cm}^{-3}$, which is typical for reduced TiO_2 crystals. At longer wavelengths, where the absorption depth increases, the quantum efficiency decreases. Thus, at 3,484 Å, where $\alpha = 1.1 \times 10^5 \text{ cm}^{-1}$ and the absorption depth is 910 Å, the quantum efficiency was measured to be 0.7 with a band bending of 0.9 eV. At this wavelength, the quantum efficiency decreases to values of 0.6, 0.5, and 0.2 at band bending values of 0.7 eV, 0.5 eV, and 0.3 eV, respectively.

The kinetics of photoelectronic injection from a semiconductor into an aqueous electrolyte depend on five time constants: τ_{recomb} , the time constant characterising the recombination rate of photogenerated electrons and holes; τ_t , the tunnelling time for charge transfer from the band

states of the semiconductor to the localised extrinsic states of the aqueous electrolyte; τ_r , the relaxation or rearrangement time characteristic of the extrinsic states of the aqueous electrolyte in going from the equilibrium condition of polarisation with the state unoccupied to the equilibrium condition with state occupied; τ'_t , the tunnelling time for charge transport from the relaxed occupied electrolyte state back into the semiconductor bands; and τ_c , the time constant for the occupied electrolyte state to undergo annihilation by chemical changes. Depending on the relative magnitudes of these time constants, various steps in the charge transfer may approach either equilibrium or irreversible conditions.

Under conditions of high quantum efficiency (0.8–1.0) as discussed above, the time constants are constrained as follows: $\tau_{\text{recomb}} > \tau_t$, $\tau'_t > \tau_t$, and $\tau'_t > \tau_c$. In other words, each photogenerated minority carrier must survive each step without appreciable probability of recombination with majority carriers, nor return to the semiconductor after injection. The latter condition is consistent with the low exchange currents observed with semiconductor electrodes¹³ and is understandable from the relaxation resulting in the occupied electrolyte state lying within the band gap of the semiconductor (see Fig. 1). The former condition is consistent with estimated values of τ_t and τ_{recomb} . The maximum tunnelling time, τ_t , can be estimated using the standard model of tunnelling¹⁴ from a potential well having a width of 200 Å (depletion width), a barrier height of 3 eV (difference between valence band edge of the semiconductor and that of intrinsic water), and a barrier thickness of 10 Å (distance of extrinsic OH^- levels from semiconductor surface). This thickness is greater than that of adsorbed OH^- ions, but less than the average inter-anion distance in the bulk electrolyte; the tunnelling rate is insensitive to the barrier thickness up to about 30 Å. In this model, carriers which have not undergone full intraband relaxation in the depletion layer ('hot' carriers) may also be injected into the electrolyte. The importance of band bending here is to confine the carriers within w , which increases the tunnelling rate. This calculation yields a value of about $5 \times 10^{-13} \text{ s}$ for τ_t . This is much faster than the estimated value of 10^{-10} s for τ_{recomb} which is calculated for bulk recombination in a direct band gap semiconductor with a majority carrier density of $2 \times 10^{19} \text{ cm}^{-3}$ (ref. 15). Surface recombination rates are more difficult to estimate.

Even faster tunnelling times would be obtained if the OH^- ion is taken to be closer to the semiconductor surface than 10 Å. For such strongly adsorbed molecular ions, a model involving a combined semiconductor-molecular ion eigenstate may be considered; this permits direct photoinjection of the hole to the OH^- ion without the necessity of a tunnelling process.

The concept of quasi-Fermi levels has been widely used in solid state physics in describing photoconductive, photovoltaic and semiconductor devices. The quasi-Fermi levels are different for electrons and for holes and describe the separate occupational probabilities for these two types of electronic particles among their respective band and defect states. The concept depends on local statistical detailed balance between the rates of creation and of annihilation of electrons and holes. For photoelectrolysis with high quantum efficiency, as noted above, local statistical detailed balance of electrons and holes is not achieved in the semiconductor near the electrolyte interface because the minority carriers are so rapidly depleted by tunnelling into the electrolyte; that is $\tau_{\text{recomb}} > \tau_t$. Therefore, the charge transfer process is better approximated as individual events. With the reverse tunnelling (exchange current) negligible, that is, $\tau'_t > \tau_t$, the charge transfer corresponds to irreversible photoinjection. This is similar, as regards irreversibility, to photoelectric emission into a vacuum; but the origin of the irreversibility is, of course, quite different.

In Fig. 1, the Fermi level of the semiconductor is shown above that of the OH^-/O_2 redox level, and it is equal to the Fermi level of the electrolyte. As O_2 is evolved at the semiconductor anode under illumination, and the concentration of OH° and other intermediate species accumulate, the reaction at the semiconductor-electrolyte interface will tend to equilibrate with the OH^-/O_2 redox level. This equilibrium will occur if the chemical depletion of OH° is slow compared to the relaxation time of OH° to its equilibrium state in the electrolyte, that is, if $\tau_0 > \tau_r$. With finite activation energy this condition is true, so that the anodic reaction in the electrolyte proceeds in approximate equilibrium with the OH^-/O_2 redox level; the absolute value of τ_r is 10^{-11} (ref. 16).

A new and simple device for the photochemical conversion of optical energy has recently been announced⁸. These devices have been labelled 'photochemical diodes', and consist of monolithic structures comprising either a semiconductor and a metal region or two different semiconductor regions (one *n*-type, the other *p*-type) which are connected through ohmic contacts. The latter is called a *p-n* heterotype photochemical diode, and it can exhibit voltage enhancement when the electron affinity of the *n*-type semiconductor is greater than the electron affinity of the *p*-type semiconductor⁹.

In accordance with the above discussion, the *p-n* photochemical diode can be described as a photocathode and photoanode, back-to-back, respectively irreversibly photo-injecting electrons and positive holes as minority carriers into extrinsic states of the electrolyte and with the majority carriers recombining in the ohmic contacts.

We thank Professor H. Gerischer for helpful comments, David Berry for independent estimates of tunnelling probabilities, and J. J. Gilman for support.

The films of CdTe were prepared by the simultaneous electrodeposition of Cd and Te on a Ti base. Presumably the process is similar to that for CdSe film formation and involves the following reactions at the cathode:

The CdTe films were prepared galvanostatically in a two compartment cell in which 2 M H_2SO_4 was used as the anolyte, a solution of 0.01 M H_2TeO_3 , 1.5 M H_2SO_4 and 0.27 M CdSO_4 as the catholyte, platinum as the anode and titanium as the cathode. The compartments were connected by a KCl-agar salt bridge.

Before use the titanium was prepared by lightly sanding the surface to remove any oxide layer and then washed in hexane to degrease the surface. The best films were prepared from a stirred solution with the composition given above and using a current density in the range 30-40 mA cm^{-2} . The films formed were black and seemed uniform in texture and thickness, an upper limit for which was 8 μm . The films adhered well to the titanium. Heat treatment at 250 °C for 16 h increased the photovoltage obtained in the photoelectrochemical cell and also reduced its series resistance.

The films were tested in a nitrogen-purged electrolyte containing 1 M NaOH, 1 M Na_2S and 1 M S. The open-circuit voltage was 0.34 V, the short-circuit current 2.6 mA cm^{-2} and the fill factor 25%. The best power conversion efficiency obtained so far is 0.4% under an irradiance of 50 mW cm^{-2} of white light from a xenon lamp with a Schott KG4 filter.

When argon-purged 5 M NaOH, containing 0.03 M partly oxidised sodium telluride, was used instead of the sulphide-sulphur solution, the photovoltage at open-current was 0.29 V, the short-circuit current density, 2.2 mA cm^{-2} and the fill factor 27%. The power conversion efficiency for the same light as before was 0.4% when the irradiance was taken as that incident on the solution. Because the solution absorbed light, the power conversion efficiency with regard to light incident on the CdTe film was between 2 and 4%. Efficiencies can no doubt be improved by varying the deposition conditions and by using cells in which there is less absorption by the solution.

The Australian Research Grants Committee is thanked for support. An Australian provisional patent application PD2052 has been lodged pertaining to this technique.

Photoelectrochemical cell with cadmium telluride film

ELLIS *et al.*¹ reported studies of single crystal CdX based photoelectrochemical cells when X = S, Se or Te and found that the best efficiencies were obtained when CdTe was used as the photoelectrode. Photoelectrochemical cells using thin films of CdS and CdSe have been reported by Miller and Heller² and by Hodes *et al.*³ In this paper, we report on a photoelectrochemical cell using a thin polycrystalline film of CdTe.

'Low scatter' conduction of electric charges through lamellar solids

MATHEMATICAL theories about the conduction of electricity through solids have been detailed for conventional metals¹. It is generally necessary to combine assumptions about the concentration of charge carriers with calculations about their probabilities of being scattered during flow. For synthetic metals the predominant scattering processes may be quite different, however. This may be so in lamellar solids after they have been converted into good electrical conductors by intercalation of electron donor or electron acceptor molecules between the layers. Such molecules are thought to form charge

transfer bonds with the two-dimensional macromolecules that constitute the layers in the parent solids before intercalation. Even static aspects of probable charge transfer bond formation have not always received complete quantum mechanical formulation. Dynamic aspects (which may influence scattering processes during current flow) are even less completely described. This letter points out that scatter probabilities of current carriers injected by charge transfer may be markedly lower than in the more familiar 'natural' three-dimensional metals. This may help to explain high electrical conductivities of lamellar synthetic metals.

Following an original hypothesis for lamellar compounds between graphite and a typical electron donor partner such as potassium, or a typical electron acceptor partner such as molecular bromine³, the remarkable increases of electrical conductivity, observed on forming intercalation compounds starting with crystalline layer lattices, were attributed to consequences of charge transfer bond formation between the giant planar carbon networks and electron donor or electron acceptor partners. Such resonance bonding may be comparatively weak, but until recently the fractional charge transfer f between partners has been only indirectly estimated. In alkali metal compounds with graphite³, just as with smaller aromatic molecules^{4,5}, volume occupancy calculations suggested that fractional charge f transfer must be near unity, but with electron acceptor partners a considerably smaller transfer seemed likely. These estimates were, however, confused by similarities in behaviour of synthetic metals⁶ such as dilute graphite-bromine, formed by direct intercalation of the halogen molecules, when compared with lamellar compounds such as graphite bisulphate formed by electrochemical oxidation⁷. In these electrochemical compounds the total quantity of electricity abstracted per g atom of graphite oxidised is accurately known. Plausibly this gives a direct measure of charge transfer fraction for electrochemical compounds. If valid, such an argument would be helpful by analogy, as electrochemical compounds are known in considerable variety⁸.

Recent optical studies⁹ give direct evidence, however, that in a lamellar compound, such as graphite-bromine, fractional charge transfer does not exceed a few tenths of 1% as most of the molecules of Br₂ are 'un-ionised'. This finding has vital consequences when interpreting the large increases of electrical conductivity (in the direction of the layer planes) on forming these synthetic metals. The structure and electrical properties of bromine-graphite are well known. A steep increase of conductivity is observed on intercalation of only very small mole fractions of Br₂ (ref. 6). The character of such increases is general for many kinds of intercalates, which at first (in dilute synthetic metals) occupy only a small fraction of the layers in the lamellar solid. Conductivity increases should apparently not be attributed specifically to any very large increase in the number of charge carriers made available per atom of carbon in the giant network conductors. To account for the high electrical conductivity of lamellar synthetic metals, the essential assumption seems to be¹⁰ that the comparatively few additional charge carriers transferred experience quite exceptionally 'low scatter' in the directions of the layer planes. At the present stage of research it might be misleading to term these lamellar solids 'super'-conductors. Cooperative effects between charge carriers are not excluded, but 'low scatter' describes the effects observed sufficiently.

The preceding remarks have been prompted by the considerable body of information on layer intercalates in graphite¹¹; however, 'low scatter' mechanisms of electrical conduction may be identifiable in other two-dimensional conductors, such as other lamellar intercalates. Even for one-dimensional, 'tunnel' or fast ion conductors scattering mechanisms seem likely to be much less effective than in conventional metals which are at least approximately three-dimensional. Whatever the nature of the solid framework in which localised charge transfer takes place, it may be important that the mobility of the molecular units from which transfer occurs remains high. They can then

participate in processes of momentum and energy exchange, together with the lighter charge carriers, when an applied voltage gradient leads to a drift of electric charge.

'Low scatter electrical conduction' parallel to the network has already been suggested by several highly unusual voltaic effects in lamellar compounds of graphite⁶. In particular, the Remote Voltaic Effect could (in one interpretation) be attributed to beams of charge carriers travelling in the lamellar solid but with each beam largely confined between its neighbouring pair of giant carbon networks; a physical analogy would be with a beam of light travelling down a curved film of glass, and unable to escape because of its total internal reflection at the air-glass surface. Unlike the transparent glass, in the lamellar compounds of graphite some general scattering seems unavoidable. Remote voltaic effects have, nevertheless, been detected over distances of several centimetres. By rigorous selection of the parent graphite specimens to be as near perfect as possible before intercalation, all these novel voltaic effects are generally more prominent and thus easier to observe. In addition to using selection criteria previously described, it is desirable to choose parent materials for which the magneto-resistance coefficient is high¹², and for which the intercalation threshold is very low¹³. Though methods for doing this are less well known, the importance of achieving low scatter by minimising structural imperfections probably also applies to diverse synthetic metals other than those based on graphite.

Study of all these effects has been greatly eased by the construction of a novel pulse meter¹⁴. This readily permits voltage gradient measurements using very large current densities up to 40,000 A cm⁻². Remote voltaic effects and other voltaic anomalies in lamellar conductors can be more readily followed with the much larger pulse currents that can now be used. The search for critical or threshold parameters is now also facilitated. Anomalous effects are not observed in the parent graphite despite its pronounced lamellar structure, but when the layers become separated by intercalation using diverse partner molecules, the marked increase in electrical conductivity and the appearance of unusual voltaic effects go side by side.

Even mass movement of the molecules themselves, acting as charge transfer partners, occurs with remarkable ease within the confinement of any intercalated layer. Some evidence^{10,11} indicates that the 'ripple potential' affecting such predominantly two-dimensional movement of molecules in a layer lattice seems far less restrictive than in most cases of mass diffusion in three-dimensional lattices and even compared with the extreme case of solid ionic good conductors (the so-called 'solid electrolytes').

Confinement to two-dimensional layers or even greater 'tunnel' restrictions on movement seems to affect markedly the electric charge carriers. Present data suggest that the unusual voltaic effects as well as the high electrical conductivity of lamellar synthetic metals are mainly due to 'low scatter conduction' of these charge carriers in the directions of the layer planes in graphite intercalates.

X-ray photoelectron spectroscopic evidence for trapped oxygen species in irradiated NaClO_3

X-RAY Photoelectron Spectroscopy (XPS) has many advantages for studying, *in situ*, the photo-induced decomposition of inorganic molecular ions; this is shown by our data on the radiolysis of NaClO_3 , sodium chlorate, using the standard Mg ($K\alpha$) anode [1,254 eV, $\lambda \approx 10\text{\AA}$] in our AEI ES200B photoelectron spectrometer. We have already examined¹ the decomposition kinetics of NaClO_4 and NaClO_3 , when the final products of irradiation were found to be a defect NaCl phase together with molecular oxygen (detected by mass spectrometry). We report here some further low temperature XPS studies on the NaClO_3 system, where strong evidence for the presence of trapped oxygen species in the initial stages of irradiation has emerged.

Powdered samples were examined in the temperature range 83–293 K using a liquid-nitrogen cooled sample-probe coupled with a resistance heater and null-point thermistor giving automatic control within ± 5 K. A base pressure of 4×10^{-10} torr in the sample chamber was achieved by previous baking of the vacuum system. An MAT AMP3 quadrupole mass analyser was connected directly to the sample chamber, and pressures were measured with a cold cathode Penning gauge situated ~ 10 cm from the sample. At any given temperature the photoelectron spectrum of an NaClO_3 sample was recorded at various times of exposure to the exciting X radiation. The core-electron levels from chlorine [Cl(2p)] and oxygen [O(1s)] were of most interest although we also routinely recorded the Na(2s), C(1s), Cl(2s) and some sodium Auger peaks as calibration checks.

The rate of decay of the original Cl(2p) and O(1s) photoelectron peaks followed 1st-order behaviour, confirming our earlier results at 253 K¹. At temperatures in the range 113–233 K the O(1s) region developed an additional peak at ~ 5 eV lower kinetic energy (higher binding energy), which grew to a limiting value with X-ray dose before decaying slowly (see Fig. 1a and 1b). The original O(1s) peak was also observed to broaden with X-ray dose as its intensity declined. A sample of irradiated NaClO_3 with an appreciable low kinetic energy O(1s) component was allowed

Fig. 1 a, Lower trace: initial O(1s) photoelectron spectrum of NaClO_3 at 203 K; upper trace: same region after ~ 180 m irradiation. b, Intensity of low kinetic energy O(1s) peak as a function of $t_{1/2}$ (obtained from Cl(2p) intensity data).

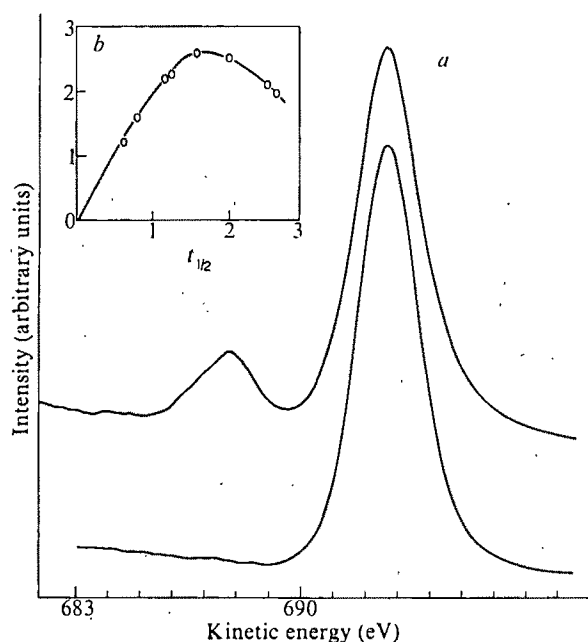

Fig. 2 Effect of raising the temperature on the O(1s) photoelectron spectrum of a sample of irradiated NaClO_3 , originally at 113 K. Sample chamber pressures were used to ensure equilibrium at each temperature.

to warm gradually to 293 K (see Fig. 2), when this feature was seen to decrease slowly, with a concomitant increase in the sample chamber pressure, due to $\text{O}_2(\text{g})$, (confirmed by intense peaks at $m/e = 32$ and 16 in the mass spectrum of the sample chamber atmosphere).

For irradiation periods much larger than the half-life of ClO_3^- , (when the Cl(2p) signal associated with the molecular ion had virtually disappeared), the main O(1s) signal remained roughly constant at $\sim 20\%$ of its initial value. A consistent interpretation of these results can only be obtained if the smaller O(1s) component is assigned to an oxygen species incorporated by the crystal lattice. The possibility that it is due to a weakly-bound oxygen molecule adsorbed on the surface was ruled out by studying the O(1s) regions of other ionic crystals which are chemically stable to ionising radiation (NaCl , Na_2SO_4). The only peaks observed had binding energies similar to the main O(1s) component in NaClO_3 ; thus the smaller O(1s) component arises solely from the induced decomposition of the molecular ion.

An electron spin resonance (ESR) study² on irradiated KClO_3 postulated the formation of molecular anions O_2^- ; which can be accommodated at vacant anion sites, providing an electron trap equivalent to the F-centre in NaCl. They exist in appreciable concentrations and show a fair degree of thermal stability. The low-intensity O(1s) component cannot be assigned to this species, however, since its intensity decreases as the decomposition of NaClO_3 proceeds, and is also very sensitive to the sample temperature. We have, therefore, assigned the residual component of the main O(1s) peak to O_2^- with a binding energy similar to that reported for oxides and chemisorbed oxygen species³.

The second low-intensity component at higher binding energy implies a small negative charge per atom. The average volume of the interstitial site in NaClO_3 (ref. 4) is $\sim 15\text{\AA}^3$ which is large enough to accommodate an oxygen atom of $\sim 12\text{\AA}^3$ volume, (calculated from the van der Waals radius). Similar considerations for the more closely-packed NaCl ⁵ structure yield an interstitial cavity of only $\sim 8\text{\AA}^3$. We cannot assign the low intensity component simply to an interstitial oxygen atom, however, because the multiplet splitting of the O(1s) level corresponding to the $^2\text{P}, ^4\text{P}$ states of the ionised atom can be calculated⁶ to be greater than 2 eV. Our observations indicate a multiplet splitting of less than 0.8 eV, which implies considerable delocalisation of unpaired spin density away from this centre. We propose that this is achieved by the formation of a loosely-bound $\text{O}_2 \cdots \text{O}$ species, between an interstitial O and an O_2^- ion at an

adjacent normal lattice site. The formal similarity of this species to the well-known ozonide anion O_3^- , the existence of which in irradiated $NaClO_3$ has been proposed from ESR studies^{7,8} supports our assignment. It should be stressed, that the formation of the $O_2 \cdots O$ complex is strongly dependent on the volume of the interstitial cavity, which must only just be large enough to trap the O atom; thus we have failed to detect any O-trapping in the low temperature radiation-induced decomposition of $NaNO_3$ (R. G. C. and J. L. unpublished).

If we suppose a step-wise process for the decomposition¹ involving $ClO_3^- \rightarrow ClO_2^- + O$ as the initial step, then the majority of the oxygen atoms will diffuse through the lattice (low trapping probability for interstitial O) to form molecular oxygen, which either escapes from the lattice, or is trapped at anion sites as O_2^- . On continued irradiation interstitial oxygen atoms will also combine with O_2^- , resulting in a slow rise in the high binding energy O(1s) peak. At long irradiation times, however, the number of oxygen atoms produced will decrease, which, when combined with a structural change to the NaCl phase (with a smaller interstitial cavity), will lead to the observed decrease in intensity. The warming-up experiment, shown in Fig. 2, can thus be explained in terms of the decomposition of $O_2 \cdots O$, and thermal diffusion of oxygen atoms which combine to form molecular oxygen.

We also observed that irradiation at the lowest temperature attainable (~ 85 K) led to no O trapping; also samples irradiated at higher temperatures and containing significant amounts of trapped O behaved exactly as in the warming up experiments on cooling to 85 K, that is, disappearance of the high binding energy O(1s) peak accompanied by the evolution of O_2 . This suggests that a structural change occurs, to a more closely-packed lattice, in the region of 85 K.

Carbon fibre structure by electrolytic etching

STUDIES of polyacrylonitrile (PAN)-based carbon fibres have demonstrated a concentric three-zone skin-sheath-core structure¹⁻⁷ originating in the oxidation of the precursor fibre before pyrolysis heat-treatment^{5,6}. I describe here an electrolytic oxidation treatment that is effective in showing up different zones in carbon fibre sections.

PAN fibres, 1.5 denier were oxidised in air at 230 °C for either 30 min or 2 h, and heat-treated at 1,000 °C, 1,400 °C or 2,500 °C giving in total six fibre types. Single tows of each fibre type were mounted in epoxy resin blocks and 3-mm thick disks were cut normal to the fibre axis. The disks were polished on one side and sputter-coated with gold on the other to make electrical connection to all fibre ends. For electrolysis the polished face was made anode in a 2 M sulphuric acid bath with carbon cathode. Longitudinal fibre sections were also prepared in a similar manner. In these, conduction through the disk is by fibre-to-fibre contact, and it was necessary to use a high-volume fraction composite of commercial type 2 PAN-based fibre rather than single tows in order to achieve sufficient conductivity. The electrolytic treatment is basically anodic oxidation. Average

current density at the fibre ends was limited to 140 A m⁻² for convenient treatment times, though neither acid concentration nor current density were found to be critical. Specimens were removed after intervals of 10–60 s, and rinsed in distilled water before microscopy.

In the initial stages of the treatment, fibre surfaces developed colours which later dulled as oxidative removal of carbon formed relief. The colours are believed to arise from interference in a thin surface layer with different optical properties, formed by intercalation of sulphuric acid into the fibre^{7,8}. As the optical path difference inferred from the interference colour increases linearly at a rate of 0.18 nm per C/m², the advancement of any particular area in the interference series is an indicator of its extent of reaction in forming an intercalation compound. The colours extend only to second order blue, which is maintained after relief is developed. Specimens were examined soon after etching as the colours fade over a period of several weeks at room temperature.

For all sections cut normal to the fibre axis the sheath etched more rapidly than the core, and increasingly so for higher heat-treatment temperatures (HTT) (Fig. 1*c-e, h-j*). In every case etching in the sheath decreases outwards, but there are differences in this gradation between HTT's. A dark ring of very etched material, approximately 1 μm wide, immediately surrounds the core in 2,500 °C HTT fibres, while the remainder of the sheath is uniformly etched at a lower rate. Fibres heat-treated at 1,000 °C and 1,400 °C show a more even outward decrease in etching of the sheath which is shown clearly by the (coloured) concentric rings in Fig. 2*b*, and the smooth contours in Fig. 1*d, e, i, j*. The core etched uniformly for all heat treatments and is seen as a plateau in fibres showing relief. In longitudinal sections both sheath and core etched uniformly, but the core more rapidly than the sheath, a reversal of the order in transverse sections (Fig. 2*a*).

Watt and Johnson⁵ have observed oxidation zones in thin sections of the PAN fibres from which the carbon fibres examined here were made. The thickness of the darker oxidised zone corresponding to the sheath increases with the square root of oxidation time (Fig. 1*a, f*) and after heat treatment the structure is apparent in polarised light^{2,3,6} (Fig. 1*b, g*). Direct comparison of the zone dimensions in oxidised and carbonised fibres is not possible because of the shrinkage from 13 to 8 μm diameter, but the relative sheath thicknesses correspond. In polarised light a Maltese cross is seen in both sheath and skin, whereas the core is optically isotropic. The contrast is lower in 1,000 °C and 1,400 °C HTT fibres but the pattern remains the same. These patterns have been interpreted in terms of the *c*-plane orientation about the fibre axis^{2,3}, which for the 8 μm PAN-based fibres is thought to be concentric in the skin, radial in the sheath and random in the core. This model agrees well with the structure seen on fracture surfaces² and in plasma-oxidised fibre sections¹, where radial striations may be seen in the sheath, and circumferential rings in the skin. Orientation is less apparent in these surfaces below 2,000 °C HTT, and it is noted that only in Fig. 1*h* (2,500 °C HTT) are there dark radial streaks in the sheath.

It is becoming evident that the sheath/core distinction is not simply one of *c*-plane orientation. Electron microscopy of crushed fibre fragments⁴, and electron diffraction studies of taper-thinned fibres² show decreasing layer-plane misorientation and decreasing crystallite stacking height from the fibre centre outwards. A uniform outward decrease is associated with the lower heat-treatment temperatures, but for 2,500 °C HTT fibre the transition takes place in a narrow 1-μm wide band; patterns which are mirrored in the etched fibre surfaces (Fig. 1*c-e, h-j*).

The thickness of the intercalated layer might be expected to vary with the inclination of the *c* planes to the surface, rising to a maximum when they are normal. If there are preferred circumferential and radial crystallite orientations any non-diametric longitudinal section will show some variation of the mean *c* plane to surface angle within zones, which might be reflected in variation of the etching rate across the zones. In fact, the zones etch uniformly (Fig. 2*a*), showing that the technique is insensitive to such orientation as may exist. Differences in crystallite mis-orientation in sheath and core will give rise to differences in plane

Fig. 1 Transverse fibre sections, air-oxidised at 230°C for 30 min (a-e) or 2 h (f-j). a,f, Thin sections of PAN fibre before heat-treatment. b,g, Polarised light, 2,500 °C HTT. c,h, Etch colours in 2,500 °C HTT fibres. d,i, Etch relief in 1,400 °C HTT fibres. e,j, Etch relief in 1,000 °C HTT fibres. Scale bar, 10 μ m.

edge density in transverse sections, but these do not seem able to account for the contrast in etch rates.

In longitudinal sections intercalation will initially take place in crystallites presenting *c*-plane edges to the surface, and the depth of penetration will be limited by the crystallite width. A higher etching rate will then be associated with wider crystallites. The core is known to have greater crystallite thickness than the sheath, and it is possible that the effective crystallite width is also greater, which would account for its higher rate of etching.

Because of the high axial *c*-plane alignment all crystallites in transverse sections will be suitably oriented for intercalation. But, the rate of intercalation is expected to be greater in the less misoriented sheath where there is greater separation of lattice distortions hindering penetration. It is probable also that axial curvature and folding of layer planes produces channels in which intercalation is facilitated, and a higher density of these may accompany the smaller sheath crystallite thickness.

These ideas come some way to explaining the reversal of sheath and core etch rates in longitudinal and transverse sections. Although the etch patterns can only be correlated with what is already known of fibre fine structure, the technique is worth pursuing as a simple and sensitive monitor of morphological variations arising during the processing of PAN fibre to carbon fibre. As such it is an aid in relating strength properties to structure, and for this application a particular advantage of

current controlled etching is the fact that insulating resin matrices are not attacked.

I thank W. Watt and W. Johnson of the Royal Aircraft Establishment, Farnborough for useful discussions and for providing carbon fibres and the photographs of PAN fibres.

Evidence for reptation in an entangled polymer melt

ENTANGLEMENTS, their nature and their role in the dynamic properties of concentrated polymer solutions and melts are not well understood^{1,2}. The classical molecular view of entanglements has been one of rope-like intermolecular couplings at a number of points along the length of a molecule; molecules in motion would drag past these couplings, the essential effect being one of enhanced friction^{1,3}. There has been a growing realisation that this model is inadequate^{2,4,5}. The essence of the problem, rather, seems to be that of the topological restrictions imposed on the motion of each polymer molecule by its neighbours: movement of a given polymer chain is constrained at the points of entanglement or intersection with adjacent chains². Theoretical treatment of the topological problem is difficult⁶, and has met only with limited success⁵. An interesting proposal regarding the motion of molecules within entangled polymer systems has been put forward by De Gennes^{4,7}: according to this, the motion of a given polymer molecule is confined within a virtual 'tube' defined by the locus of its intersections (or points of 'entanglement') with adjacent molecules (Fig. 1). The molecule is constrained to wriggle, snake-like, along its own length, by curvilinear propagation of length defects such as kinks or 'twists'⁸ along the tube; this mode of motion has been termed reptation⁴ (from reptile). Reptative motion clearly satisfies the central requirement of entangled systems: that of the non-crossability by a given chain of the contours of its adjacent

Fig. 1 A polymer chain in an entangled melt (or concentrated solution) may be regarded as being within a virtual 'tube' defined by the locus of its intersections with other melt molecules, as indicated. The obstacles defining the 'tube' in the lower figure are sections through the melt molecules in a plane parallel to the paper. For clarity, the density of segments shown is much lower than would be the case in a real melt.

neighbours. In a real polymer melt the topological environment of any given molecule (that is, the virtual 'tube' surrounding it) will itself change with time. This is because the adjacent molecules defining it are themselves mobile. If this reorganisation is sufficiently slow then the translational motion of the enclosed molecule will be effectively curvilinear (reptative). Consideration of the problem⁹ suggests that this will be the case in an entangled system. One then expects translational diffusion to be dominated by reptation. There is no direct experimental evidence supporting the physical reality of curvilinear motion in entangled polymer systems. I report here the results of experiments on diffusion within a polyethylene melt critically designed to test the reptation concept.

One outcome of constraining a polymer chain of random walk configuration to diffuse, by Brownian motion, within a confining (virtual) tube, is that the translational diffusion coefficient D scales as

$$D \propto M^{-2} \quad (1)$$

where M is the molecular weight. This may be readily proved⁴, and is a direct consequence of imposing a random walk configuration on the essentially one-dimensional curvilinear diffusion of the molecule along its own contour.

Previous studies of self-diffusion in concentrated polymer solutions and in melts have involved mainly the use of NMR¹⁰⁻¹⁴ and radio-tracer techniques¹⁵⁻¹⁷. The results of the NMR studies are ambiguous, as it is difficult to separate the contributions to the overall motion due to translation of the molecule as a whole from those due to the internal (segmental) motion^{11,13}. McCall *et al.*¹⁰, for example, using the NMR

technique, have estimated the diffusion coefficient in molten polyethylene to vary as $D \propto M^{-5/2}$; their result, however, was based on rather limited data. In the case of the radio-tracer studies involving the variation of D with diffusant length in polymer melts, the results^{15,16} have been of a somewhat qualitative nature and have lacked a discriminative character.

In the present experiments the translational diffusion coefficient D of a series of deuterated linear polyethylene (DPE) fractions was measured in a protonated linear polyethylene (PPE) melt. Neutron scattering studies^{18,19} of polyethylene melts, in which small amounts of DPE were dissolved in PPE (and vice versa), indicate that the radius of gyration of the minor component in the melt is consistent with its having a random coil configuration. Thus if translational diffusion of the DPE molecules within the PPE melt is taking place by reptation, the relation of equation (1) must hold: and this is what I set out to test.

The measuring technique was developed by B. J. Briscoe and myself, and is based on infrared (IR) microdensitometry; it is described in detail elsewhere²⁰. In essence, the technique involves setting up a concentration step-function of the diffusant of interest within the matrix, and allowing it to broaden, with time, under diffusion. Measurement of the final diffusion broadened profile is carried out using an IR microdensitometer, which yields a value for D . The diffusant must absorb at some IR frequency unaffected by the matrix: in the present case, the labelling frequency was that of the C-D stretching mode (in DPE) at $2,170 \text{ cm}^{-1}$, a region free of absorption by the PPE.

Five fractions of linear DPE (98% deuterated) were used. Table 1 shows their molecular weight characteristics, as determined by gel permeation chromatography. The PPE matrix was linear polyethylene of $M_w = 1.6 \times 10^5$, $M_w/M_n \approx 15$ and $\text{CH}_3/1,000\text{C} < 1$; this molecular weight is much higher than the critical molecular weight for the onset of 'entangled' behaviour, as deduced from viscosity and other measurements^{1,2}. Solid solutions, 2% w/w, of each DPE fraction in the PPE matrix were prepared by dissolving and mixing both components in boiling xylene; the mixture was then precipitated from solution by pouring into cold excess methanol. After washing and drying, pellets were moulded from these precipitates and from pure PPE which had been similarly dissolved and precipitated, and these were coherently joined²⁰ to form composites containing a step function in DPE concentration (Fig. 2a). The composites were placed in suitable PTFE containers inside sealed glass ampoules under nitrogen, and left for various lengths of time at the diffusion temperature. On quenching (thereby effectively stopping further diffusion), slices were taken from the composites and scanned in the IR microdensitometer²⁰ to yield the diffusion broadened profiles (Fig. 2b).

Evaluation of D for a diffusion broadened step function is straightforward when dealing with a single diffusing species²¹. When a diffusant is not monodispersed, however, difficulties arise in interpreting the experimental data. This problem has led to serious anomalies in previous studies of self-diffusion, mainly with NMR techniques^{11,12}. In the present case, the final broadened profile (such as in Fig. 2b) is the sum of contributions from species of different molecular weight (within each DPE fraction, see Table 1), and hence different D values. If a diffusing species of molecular weight = M_i has a diffusion coefficient D_i associated with it, such that $D_i \propto M_i^{-\alpha}$, then analysis shows (J.K. in preparation) that the slope of the broadened step function at the position of the original interface (Fig. 2b) is the experimental quantity which is to be measured. This yields an overall diffusion coefficient \bar{D} associated with a diffusion-average molecular weight, M_D , such that

$$\bar{D} \propto M_D^{-\alpha} \quad (2)$$

where

$$M_D = \left(\sum_i w_i M_i^{-\alpha/2} \right)^{-2/\alpha}$$

Characteristics were determined by gel permeation chromatography. N_w is the weight-average degree of polymerisation, corresponding to M_w .

Table 1 Molecular weight characteristics of the deuterated polyethylene (DPE) fractions.

Fraction	M_w	M_w/M_n	(N_w)
DPE1	3,600	2.25	(225)
DPE2	4,600	2.2	(288)
DPE3	11,000	3.4	(688)
DPE4	17,000	2.2	(1,063)
DPE5	23,000	1.8	(1,438)

w_i are the weight fractions of each species M_i comprising the diffusant sample.

In Fig. 3 M_w is plotted against the diffusion coefficient \bar{D} as measured from the slope of the diffusion-broadened profiles such as in Fig. 2b. The best fit to the data is

$$\bar{D} \propto M_w^p \quad (3)$$

where $p = -2.0 \pm 0.1$. But for $\alpha = -2$, M_D becomes identical with M_w : for consistency of equations (2) and (3), therefore, α must be identified with p .

Thus for a DPE molecule of molecular weight M , diffusing in an 'entangled' PPE melt, the translational diffusion coefficient D scales as

$$D \propto M^{-2 \pm 0.1}$$

This result is to be compared with the reptation relation of equation (1); it may be contrasted with the relation $D \propto M^{-3.5}$ expected on the basis of, for example, Bueche's entanglement-coupling model.

These results provide direct experimental support for the suggestion that the translational diffusion mode of polymer molecules in 'entangled' melts is a curvilinear one. This has a number of implications.

Fig. 2 Typical concentration profiles of deuterated polyethylene (DPE) in the protonated polyethylene matrix (PPE). *a*, Immediately subsequent to creation of a step-function. $C_0 = 2\%$ w/w of fraction DPE3 in PPE. The broken line represents an ideal step-function, and the continuous line is the profile as scanned in the infrared microdensitometer¹⁸. The scanning frequency is that of the C-D stretching mode at $2,170 \text{ cm}^{-1}$. *b*, The concentration profile of (*a*) following a diffusion run. Diffusion temperature $T_D = 176.0 \pm 0.3^\circ \text{C}$; $t_D = 1.114 \times 10^6 \text{ s}$; D as evaluated from the slope at the position of the original interface, is $3.7 \pm 0.6 \times 10^{-9} \text{ cm}^2 \text{ s}^{-1}$. The broken curve is the theoretical Fickian profile for a single diffusing species with the diffusion coefficient D ; the deviations from the experimental profile are due to the polydispersity of the actual diffusant sample (see text and also equation (2)).

The effect of 'entanglements' on the slow relaxation modes in 'entangled' systems now seems to be clearer: the slowest of these modes corresponds to the centre-of-mass translational diffusion of the molecules, and is constrained to take place by reptation. The concept of localised entanglement coupling at a relatively small number of points, which lay at the heart of classical theory, must give way to the view where the effect of entanglements is one which pervades the length of a molecule: the net result is one of topological constraints on the motion of molecules. For sufficiently high molecular weight, curvilinear motion alone is allowed.

It is tempting to suggest, in view of these results, that the onset of snake-like motion corresponds also to the onset of entangled behaviour. This suggestion is explored elsewhere⁹. Within the range of experimental parameters described,

Fig. 3 The variation of \bar{D} with M_w for deuterated polyethylene diffusing in a protonated polyethylene matrix, at a diffusion temperature of $176.0 \pm 0.3^\circ \text{C}$. Each point represents a separate experiment, and is the mean of 10 separate profiles such as in Fig. 2b. The lengths of experimental runs (t_D) vary by a factor of ~ 3 within each pair of experiments for a given DPE fraction. The least-squares best-fit to the data is the relation:

$$\bar{D} = 0.2 M_w^{-2.0 \pm 0.1}, \text{ and is shown.}$$

however, the results clearly support De Gennes' notion of reptation in an entangled polymer system.

I thank Professor Sir S. F. Edwards for stimulating discussions, Dr D. G. Ballard and Dr G. Longman for supplying the deuterated fractions, and Professor D. Tabor and Dr B. J. Briscoe for their encouragement. A grant from Dow Corning Chemicals and a Research Fellowship from St Catharine's College, Cambridge, are both gratefully acknowledged.

Improving the timbre and responsiveness of a bass trombone

THE design of brass instruments has always been a largely heuristic procedure. Recently, however, a knowledge of the acoustic impedance of the instrument has been used to correct faulty intonation in a trumpet¹. Here we demonstrate how such knowledge may be used to improve both the timbre and the responsiveness (or 'feel') of a bass trombone.

Bass trombones commonly use one or more valves (in addition to the slide) to increase the length of the instrument, thereby reducing the playing frequency. The instrument used in this experiment possesses a 'G valve' which lowers the pitch of a Bb instrument by three semitones. It follows, therefore, that the note G2 (98 Hz) may be played in two ways, either (1) the slide in 1st position and the valve depressed; or (2) the slide in 4th position and the valve released. In both cases the overall length of the instrument is the same, but the extra tubing is introduced at different points. J.M.B. noted that using the valve to play G2 resulted in a note that was difficult to sustain comfortably, and that this difficulty further manifested itself in a marked deterioration of the timbre.

The acoustic impedance of the instrument with all its tuning slides fully in was measured for both of the above cases, using apparatus described elsewhere². The results are shown in Fig. 1. The plots are similar, but the fundamental of G2 (which is the second maximum) is flatter by 6 Hz using the valve. There are also differences between the amplitudes of the maxima, but we shall confine ourselves to matching the frequencies of the fundamental as closely as possible for the two cases. The need to do so is explained by Benade³. Since the sound generating mechanism of brass instruments is non-linear, it may be shown that all the maxima which lie close to integral multiples of the playing frequency interact to sustain a note to an extent depending on the playing dynamic. This interaction is referred to by Benade as a "regime of oscillation". When using the valve to play G2 the fundamental is too flat for a truly successful 'regime' although the remaining maxima are reasonably well positioned. What is required then, is to raise the frequency of the fundamental when the valve is used without altering the positions of higher maxima.

Wogram⁴ introduces the concept of a 'sum function' which he calculates by determining the real part of the input impedance, and then summing the input resistance values at harmonics of a given fundamental frequency. He further shows that the peaks of this 'sum function' are simply related to the playing frequencies of an instrument,

Fig. 1 The acoustic impedance of the instrument before modification. Using the valve (dashed line); not using the valve (solid line).

Fig. 2 The internal spectra of the modified instrument *a*, ff; *b*, pp.

and thus enable one to study the way the playing frequency changes with playing dynamic in a systematic manner. We have also written a computer program which calculates the internal spectrum for any playing frequency but in particular the ones predicted by the peaks of the 'sum function'. When the 'sum function' is calculated for the bass trombone using the valve it is found that at high dynamic levels the playing frequency is 103 Hz but at low levels it falls to 94 Hz and the internal spectrum envelope deteriorates considerably (see Fig. 2). Interestingly the change of playing frequency also appears when 4th position is used, though to a smaller extent, indicating that the possibility still remains of affecting further slight improvements to the whole instrument.

A perturbation theory exists to move the positions of the resonances of the trumpet¹ and a simple scaling procedure enables it to be used for a trombone. Clearly it is necessary to restrict the changes only to the G valve section so that the parts common to the Bb and G instruments are unaffected. Calculations indicated that a 9% reduction in the cross-sectional area of the tube forming the G valve was required. A new section was, therefore, fitted, and the acoustic impedance was again measured. The results indicate a considerable improvement although the fundamental is still 3 Hz too flat.

To determine whether any real subjective improvement had been made, a professional bass trombone player was invited to compare this instrument with an unmodified one whose impedance curve was measured and found to be identical (within experimental error²) to the results shown in Fig. 1. The player wore a blindfold and heavy gloves during the experiment, and the slides of both instruments were cleaned and oiled so that they felt as similar as possible. (This precaution is necessary because musicians are strongly influenced by the slide quality⁵.) The player was presented with a pair of instruments sequentially. Each pair was either a repetition of a given instrument or the two different instruments. The player was then instructed to play the note G2 under both conditions (with and without the valve) and then state whether he thought they were the same or different. If he thought they were different he was then asked which one of the pair he preferred. During extensive trials he could always distinguish between the two different instruments, and always correctly identified the repetitions. He referred to the unmodified instrument as "stuffy", "dull", and "hard to play" when using the valve. He greatly preferred the modified instrument and stated that the two playing conditions were "as closely matched as possible".

Thus the timbre and responsiveness, in addition to the intonation, may be improved given an apparatus for measuring acoustic impedance, and a theory which relates the geometry of the instrument to the frequency distribution of the impedance maxima.

Guinea Current upwelling

THE historical record of maritime observations are summarised here to indicate the dominant seasonal variations in upwelling, and in certain associated processes, within the Guinea Current region. The region is similar to other eastern ocean boundary upwelling areas in the appearance of cool sea temperatures near the coast, productive coastal fisheries, and a zone of low rainfall on the adjacent coast (Fig. 1). It differs from some of the more studied regions in several important respects. These include the zonal rather than meridional trend of the coast, the influence of a rather narrow intense coastwise current, and an unusual lack of correspondence on the seasonal time scale between sea-temperature features attributable to upwelling, and features in the overlying wind stress field¹. There seems to be a link between interyear variations in upwelling intensity and corresponding variations in both coastal rainfall and local fishery success.

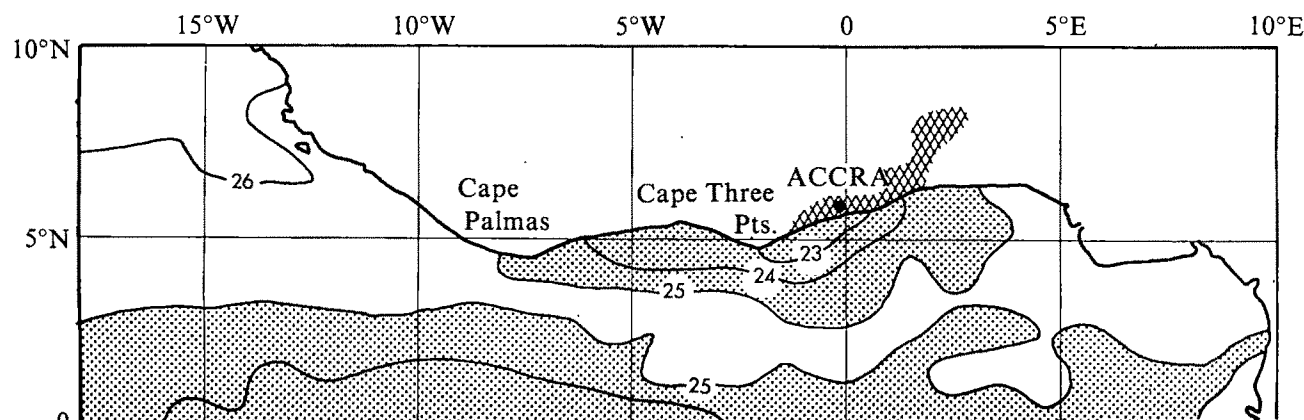

To construct the sea-temperature distribution shown in Fig. 1, maritime reports for the period 1850–1970 were obtained from the U.S. National Climatic Center's file of marine surface observations (TDF-11), checked for gross errors, and summarised by month and by 1° 'square' areas. Mean values were contoured by hand, taking into account the abundance of observations and magnitude of standard deviations. Data abundance was greatest near the coast and to the west of Cape Palmas. The effect of warm advection in the eastward-flowing Guinea Current is apparent in the shape of the 26 °C isotherm and in the offshore temperature

maximum which separates the cool temperatures along the coast east of Cape Palmas, attributable to coastal upwelling, from cool temperatures near the equator which are probably related to equatorial upwelling.

The seasonal distribution of sea-surface temperature within a line of 1° square areas stretching southward from the coast near Cape Three Points (Fig. 2) features an offshore maximum every month, suggesting continuation of some degree of coastal upwelling throughout the year. The offshore gradients are most intense from June through October; coolest coastal temperatures are reached during August and September. A secondary coastal minimum appears during January, resulting in a two-peaked annual temperature cycle.

A similar display of the seasonal cycle of sea-surface temperature (Fig. 3), this time within a line of 1° square areas arranged along the coastal boundary, reveals continuity of the summer minimum along the entire north coast of the Gulf of Guinea. In Fig. 3, west is towards the top (see Fig. 3d); thus the direction of flow of the Guinea Current is from the top towards the bottom of the diagram. The temperature decreases in the direction of flow to an absolute minimum east of Cape Three Points. Although the contour interval in Fig. 3 is too coarse to show it, much of the temperature decrease occurs in two abrupt steps upon passing each of the two major capes, Cape Palmas and Cape Three Points. Particularly sharp temperature gradients have been reported off Cape Palmas². The coolest region, defined by the 24 °C isotherm, appears in Fig. 3 to be split into two lobes by slightly higher temperatures from 0–1°W longitude; this is an artefact due to that particular 1° square being displaced slightly offshore relative to the squares to either side. Eastward of this late summer minimum feature, sea-surface temperature increases towards a region increasingly affected by outflow from the Niger River Delta and other sources. A cold temperature feature is apparent during winter in the extreme western portion of the region. The sharp gradient near 15°W longitude indicates the southern limit of the tropical front which oscillates seasonally along the west African coast between 10°N and 20°N latitudes, apparently responding to seasonal variations in wind-induced upwelling and associated along shore advection³. Extending eastwards from the front is a winter temperature minimum which retains its identity along the Guinea Coast well into the Bight of Biafra (~7°E longitude) where it is evident as a slight reversal during January. The two seasonal temperature minima are separated by periods of relatively warm sea-surface temperatures, with the major maximum occurring during spring.

Fig. 1 Long-term mean distribution of sea-surface temperature, summarised by 1° square areas for August. The contour interval is 1 °C; temperatures less than 25 °C are shaded. The crosshatched area on the coast in the vicinity of Accra indicates an area of less than 40 inches annual rainfall, and defines the approximate extent of the Accra dry belt¹⁶.

Fig. 2 Long-term composite annual cycle of sea-surface temperature within the line of 1° squares normal to the coast near Cape Three Points shown to the right. The contour interval is 1°C ; temperatures less than 25°C are shaded, and those greater than 28°C are indicated by broken diagonal hatching. The location of the maximum mean temperature within the line of squares for each long-term monthly sample is indicated by the dashed line.

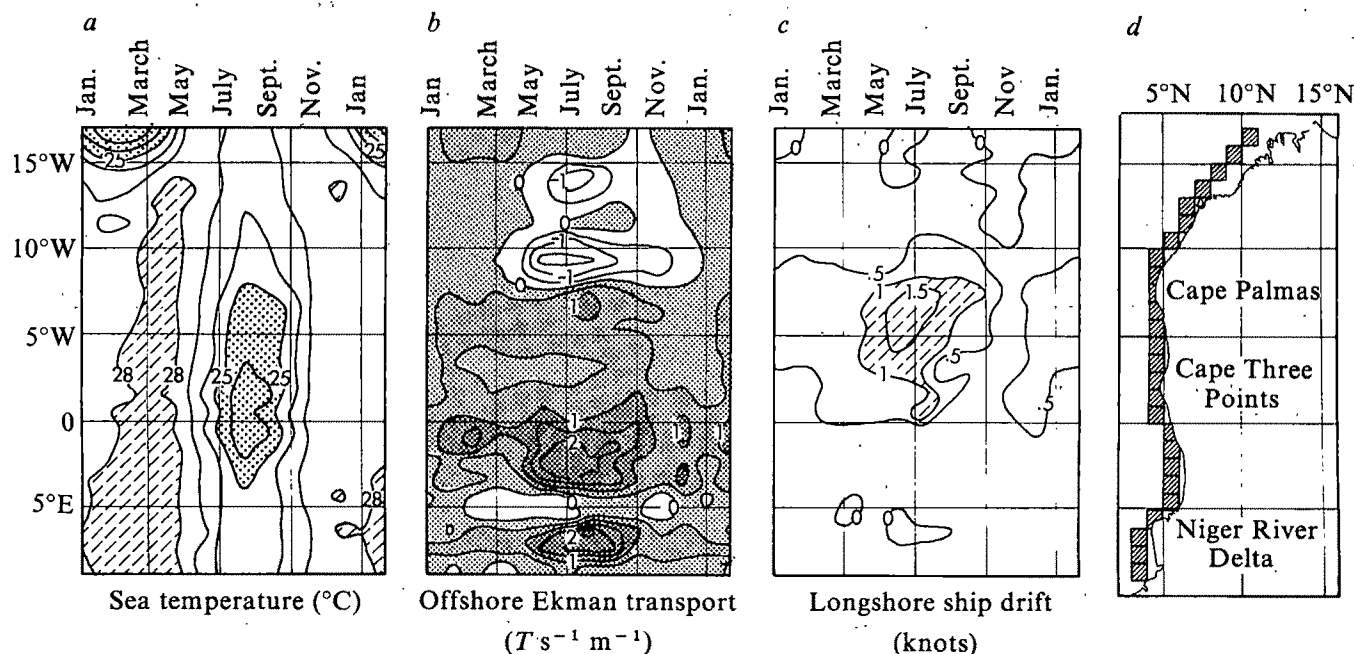

Being near the equator, the Guinea Current region experiences two periods of vertical sun per year, one shortly before the vernal equinox and the other shortly after the autumnal equinox. Unlike the situation in more temperate latitudes, both solstices are periods of low sun. Thus, the double peaked seasonal cycle of sea temperature matches qualitatively the cycle of solar height. But compilations of mid-ocean sea-surface temperatures¹, at similar latitudes where the cycle of solar height is identical, indicate no such strong correspondence. Thus, it is difficult to ascribe the observed features directly to such large scale effects as passages of the Sun. Rather, they would seem to be almost entirely controlled by processes local to the Guinea Current region.

In the classical model for coastal upwelling², water set in motion by the stress of the wind is deflected offshore by the rotation of the Earth. When this occurs along an extensive stretch of coast such that the water transported off

the coast cannot readily be replaced by convergence of horizontal alongshore flow, replacement can occur by upwelling of deeper water.

Previous comparisons of offshore Ekman transport distributions with corresponding temperature distributions in the California Current³, and Canary Current⁴ regions on a similar 1° scale have yielded general conformities in major features, indicating seasonal variation in the local wind as the principal factor controlling seasonality in the coastal upwelling process. Accordingly, wind reports from the Guinea Current region were assembled from the same source as the temperature reports. These were converted to measures of sea-surface stress by squaring each reported wind speed and multiplying by the density of air (assumed constant, 0.00122 g cm^{-3}) and a constant drag coefficient (0.0013). The derived stress 'reports' were then averaged by components to yield a resultant mean stress for each long term composite month and 1° square area. This was con-

Fig. 3 Long-term composite monthly variations within the 1° square areas arranged along the coast, shown in (d). a, Sea-surface temperature. The contour interval is 1°C ; temperatures less than 25°C are shaded and those greater than 28°C are indicated by broken diagonal hatching. b, Offshore-directed component of Ekman transport. The contour interval is 0.5 tonnes S^{-1} transported across each 1 m width. Positive values, indicating seaward transport, are shaded; darker shading indicates more intense seaward transport. c, Alongshore component of ship drift. The positive direction is such that the coast is on the left when facing downstream. The contour interval is 0.5 knots ; speeds greater than one knot are indicated by broken diagonal hatching.

verted to Ekman transport, directed 90° to the right of the stress vector, by dividing by the Coriolis parameter computed at the mid latitude of the 1° square. Where the centre of the square is less than 5° from the equator the value of the Coriolis parameter at 5°N latitude was used. Offshore components were resolved along characteristic offshore normal directions, based on the nearshore bathymetry within each individual square.

The seasonal pattern of offshore-directed Ekman transport (Fig. 3) reveals certain features which correspond to features in the temperature pattern. Transport tends to be offshore throughout the year, except during certain months off Liberia and Sierra Leone ($8\text{--}14^\circ\text{W}$) and near the west-facing portion of the Niger River Delta shoreline ($4\text{--}6^\circ\text{E}$). A winter maximum of offshore transport occurs in March at the northwestern end of the area (top of the diagram), and retains continuity toward the east, shifting to February off Cape Palmas and Cape Three Points. This winter maximum generally corresponds to the winter temperature minimum described above. During the summer there is a relative maximum of offshore Ekman transport on the east side of Cape Palmas and another increase to the east of Cape Three Points; these correspond to the major decreases in sea temperature near these capes.

Maximum values of offshore transport occur to the east, however, that is downstream in relation to Guinea Current

observations produced as part of this study show a very significant component of the mean wind to be directed onshore at all seasons. Any larger portion of the transport being directed with the wind would, therefore, only imply a further reduction in local wind forcing of upwelling at the coast.

Figure 3c summarises reports of drift attributed to ocean currents compiled from ship's logbooks by the U.S. Naval Oceanographic Office. Although the number of available reports is very small, being of the order of 20 per month-square in the area from Cape Palmas to Cape Three Points, a coherent picture of the seasonal cycle of flow in the Guinea Current is apparent. Off Cape Palmas the current near the coast intensifies dramatically, diminishes slightly toward Cape Three Points, and drops off rapidly past Cape Three Points. Mean velocities near Cape Palmas vary from nearly 2 knots in July to less than half a knot in November. The current maximum is thus somewhat upstream of and slightly preceding the summer temperature minimum, actually coinciding in time to the period of most rapid temporal decrease of temperature and in space to the zone of most rapid spatial decrease. Horizontal advection in the current, of course, opposes the temperature decrease. Various mechanisms leading to vertical advection in an intensified current⁷⁻¹⁰ could perhaps contribute to the observed cooling. But, the lag of at least a month between

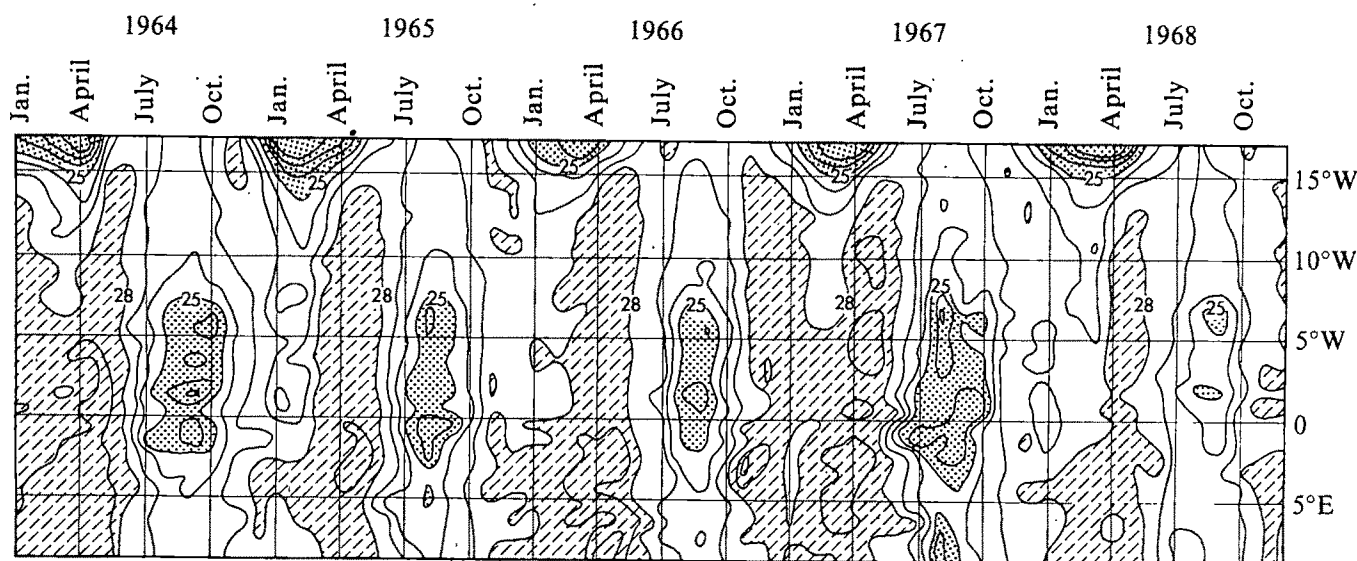

Fig. 4 Monthly temperature variation within the square areas shown in Fig. 3, during the years 1964 through 1968. The contour interval is 1°C ; temperatures less than 25°C are shaded and those greater than 28°C are indicated by broken diagonal hatching.

flow, of the location of summer minimum temperatures. The offshore transport maximum off Dahomey ($2\text{--}4^\circ\text{E}$) is in the area of most rapid down-stream warming. Likewise, a second offshore transport maximum in the Bight of Biafra ($6\text{--}9^\circ$) is not strongly reflected in the sea-temperature distribution, although both cases may involve some masking of the effects of upwelling by low salinity surface water. Certainly, there is nothing in the local Ekman transport distribution to account for the continuity of the temperature minimum to the west, that is, upstream, of Cape Palmas.

Since this region is very near the equator, the diminished Coriolis term in the dynamical equations may lead to a different balance of forces from that assumed in the Ekman transport relationship. In such a case the transport could be at a lesser angle than 90° to the direction of wind stress. Such an effect, however, cannot explain the non-correspondence of the distributions in Fig. 3. Summaries of wind

the maximum current speed in July and the minimum sea-surface temperatures in August–September (Fig. 3) is difficult to reconcile with any predominant effect of such processes; for example, at the indicated average current velocities, water upwelled near Cape Palmas during the July current maximum would be carried past Cape Three Points in less than 10 days.

Recent theoretical developments have indicated the ability of upwelling-produced displacements of the internal density structure to propagate in the form of coastal trapped waves, and thus to affect the temperature and current velocity fields at other locations along the coast^{11,12}. In the configuration of the Guinea Current region, the direction of propagation would be to the west. The degree of westward displacement of features in the sea temperature and drift patterns, compared to features in the Ekman transport field (Fig. 3), is consistent with computations from theory

Table 1 Comparison of intensity of summer-fall upwelling with July–October rainfall at three reporting stations in Ghana and with catch of the Ghanaian herring fishery for the years 1964 through 1968

		1964	1965	1966	1967	1968
Upwelling		High (late)	Intermediate	Intermediate	High	Low
Month		J A S O*	J A S O	J A S O	J A S O	J A S O
Rainfall (quintiles)	Accra	3 1 0 0	5 5 3 2	4 3 1 3	1 2 5 1	6 6 6 5
	Takoradi	2 4 1 0	4 4 5 1	5 4 2 2	2 2 3 1	6 6 6 5
	Kumasi	3 4 1 2	4 5 3 5	6 5 1 2	2 1 2 1	6 6 6 1
Summation		21	46	38	23	65
Herring catch (Ghana)		34.2	7.8	13.3	43.2	12.2

Upwelling intensity is estimated from sea-temperature distributions (Fig. 4). Rainfall is given in quintiles of the frequency group within which the recorded precipitation falls relative to a group of reference years¹⁷. 0 indicates monthly precipitation to have been lower, and a '6' indicates it to have been higher, than in any corresponding month in the reference series. In the line labelled summation the quintile values for the four months and the three stations are added together to give a seasonal index. The herring catch is in 10³ tonnes.

*J, July; A, August; S, September; O, October.

(A. J. Clarke, personal communication). Thus it seems that such processes may be exerting particularly strong control on the pattern of seasonal upwelling in the Guinea Current.

In the surface marine observation file (TDF-11) there is an abrupt increase in the density of reports in the Guinea Current region beginning with 1964. In the particular version of the file that was used in this study, however, the frequency begins to drop off rapidly after 1968. For these five years of maximum data density a time series of sea-surface temperature (Fig. 4) was constructed on the same basis as the long-term composite annual cycle (Fig. 3). Because of the higher short-term variance of the wind, the data density was not sufficient to derive a meaningful similar series of wind or Ekman transport variations.

If one examines the summer upwelling feature (10°W–5°E longitude) in Fig. 4, it is possible to class the summers of 1964 and 1967 as having been cold (strong upwelling), 1968 as having been warm (weak upwelling), and 1965 and 1966 as having been intermediate (Table 1). In addition the strong upwelling in 1964 seems to have occurred relatively late, the coolest monthly mean temperatures appearing in September rather than in August as is the case in long-term composite cycle (Fig. 3). In partial corroboration of this classification, dissolved oxygen data collected off Ivory Coast (~4°W) during the period 1966–70¹³ show low oxygen values characteristic of deeper layers unmistakably nearer the surface during the summer upwelling season of 1967 than in the other years of that particular series.

With these upwelling estimates, it is possible to look for apparent effects of upwelling variations on coastal rainfall. One mechanism which may contribute to the intense coastal aridity, which is a general characteristic of upwelling regions, is the stabilisation of the shoreward airflow by the cool upwelled surface waters, thereby inhibiting vertical development of storm clouds¹⁴. The Accra dry belt (Fig. 1), which has the appearance of a coastal enclave of semi-arid savanna surrounded by tropical rainforest, has been termed 'the most remarkable climatic anomaly of the Guinea coastlands'¹⁵. One of the unusual features cited is an anomalous dearth of rainfall during the late summer. Prevailing winds are from the south-west¹⁶; Figure 1 shows the Accra dry belt to be oriented directly downwind of the coldest sea-surface temperatures.

Table 1 classifies the rainfall recorded at three locations in Ghana¹⁷. Takoradi is located on the coast, just east of Cape Three Points. Kumasi is about 100 miles inland, between Takoradi and Accra. The correlation of the rainfall record with the upwelling estimates is convincingly strong. During the years of strong upwelling, 1964 and 1967,

the July–October rainfall was anomalously low; in fact 'late' upwelling estimated for 1964 corresponds to 'late' rainfall deficits in September and October. During the weak upwelling year, 1968, monthly mean rainfall actually exceeded the highest class intervals established from historical data at all three locations during the months of July, August, and September.

Also listed in Table 1 are the landings of herring (*Sardinella aurita*) in Ghana during these same five years¹⁸. This was Ghana's most important fishery during this period, largely operating from canoes very near shore during the summer-fall upwelling period¹⁹. Evidently periods of extremely good fishing were associated with strong upwelling, as are periods of subnormal coastal rainfall. During these years a sharply increased trend in fishing effort occurred, due to technology and so on. If this is taken into account in interpreting the landing figures, a relationship is even more apparent.

The origin and relative abundances of C, N and the noble gases on the terrestrial planets and in meteorites

RASOOL and Le Sergeant¹ adopted the inhomogeneous accretion model for planets discussed by Turekian and Clark² and considered the question of whether carbonaceous chondrites or LL chondrites could better explain the relative abundances of volatile elements found on Earth and Mars. In the inhomogeneous accretion model the volatile elements of the terrestrial

planets are attributed to a component which is added late in the accretional history of the planet. Turekian and Clark² presumed this late-stage component to be like carbonaceous chondrites. But, Rasool and Le Sergeant¹ compared the relative concentrations of H, C, N, Ne, Ar, Kr, and Xe (normalised to C) for the Earth, C1 (carbonaceous) chondrites, and LL (ordinary) chondrites and concluded that relative volatile abundances for the Earth have greater similarity to LL chondrites than to C1 chondrites. Specifically, these authors noted that relative to carbon, abundances of the noble gases (Ne, Ar, Kr, and Xe) are within a factor of 3.8 for the Earth and LL chondrites, but differ by factors of 15–37 between the Earth and C1 chondrites. Abundances of H and N relative to C were indicated to be the same within a factor of 2.5 for both meteorite types and the Earth. Turekian and Clark² had previously made similar comparisons between the Earth and C1 chondrites and concluded that terrestrial volatiles were acquired from material having H/N/C ratios similar to C1 chondrites, but with order-of-magnitude higher abundances of the noble gases. Rasool and Le Sergeant, on the other hand, concluded that volatiles on Earth and, by extension of their arguments, also volatiles on Mars can better be explained by late accretion of material similar to LL chondrites rather than material similar to C1 chondrites. We disagree with the conclusion reached by Rasool and Le Sergeant and with the LL-chondrite data which they used to reach their conclusion. Our purpose here is to demonstrate (1) that the noble gas/C and noble gas/N ratios presently determined for the Earth differ by an order of magnitude from these ratios in most meteorites; (2) that as a group LL chondrites show no better agreement with the Earth in these ratios than do C1 chondrites; (3) data are too incomplete to lead to any conclusions about the type of meteoritic material which may have supplied volatiles to Mars. In addition we suggest that the noble gas/C and noble gas/N ratios for Venus are likely to be more like the Earth's than like meteorites.

Figure 1 plots ^{36}Ar concentrations against the $^{36}\text{Ar}/\text{C}$ ratio given in units of 10^{-8} cm^3 per g weight % for several types of meteorites. The major trend is for the $^{36}\text{Ar}/\text{C}$ ratio to decrease as the ^{36}Ar concentration decreases, which probably reflects either different formation temperatures, or the greater ease by which ^{36}Ar can be lost from material compared to C. The LL chondrites of petrographic grades 4–6 have ^{36}Ar concentrations two orders of magnitude lower and $^{36}\text{Ar}/\text{C}$ ratios a factor of ~ 1 –3 lower than carbonaceous chondrites. Other ordinary H and L chondrites of the same petrographic grades have very similar ^{36}Ar and C contents to the LL chondrites shown. Unequilibrated chondrites (ordinary chondrites of petrographic grade 3) have intermediate ^{36}Ar concentrations and seem to show the greatest range in $^{36}\text{Ar}/\text{C}$ ratios among the various meteorite types. But, the two highest $^{36}\text{Ar}/\text{C}$ ratios shown for unequilibrated chondrites (Krymka at 185 and Chainpur at 124) must be considered dubious, as separate ^{36}Ar analyses on these meteorites showed variations up to a factor of 10. A separate analysis of Chainpur gives the data plotted at $^{36}\text{Ar}/\text{C} = 20$. Ureilites, whose ^{36}Ar is associated with diamond and graphite, have the highest ^{36}Ar concentrations of any meteorite type. The two Murchison (C2) data points are acid-etched, nonsilicate residues containing $\sim 50\%$ organic polymer C, but comprising only ~ 1 –2% of the total meteorite. Several analogous acid-etched residues from Allende (C3) showed amorphous C contents of ~ 18 –97% and $^{36}\text{Ar}/\text{C}$ ratios of ~ 2 –10, with one value of 97 (ref. 4). No substantial data exists which indicates $^{36}\text{Ar}/\text{C}$ ratios in meteorites higher than $\sim 100 \times 10^{-8} \text{ cm}^3$ per g weight %.

In comparison to the meteorite data in Fig. 1, the ^{36}Ar concentration and $^{36}\text{Ar}/\text{C}$ ratio for the whole Earth have been estimated as $2.1 \times 10^{-8} \text{ cm}^3 \text{ g}^{-1}$ and 473 (10^{-8} cm^3 per g weight %) respectively², and plot far off Fig. 1 to the right. The $^{36}\text{Ar}/\text{C}$ ratios for the Sun⁴ and the atmosphere of Mars⁵ are larger than this ratio for the Earth by factors of 5×10^5 and 23, respectively. Individual meteorites have $^{36}\text{Ar}/\text{C}$ ratios lower by factors of 5–100 relative to the Earth. Considering the average $^{36}\text{Ar}/\text{C}$ of different classes of meteorites compared to the Earth, C1s are

Fig. 1 Relationship between ^{36}Ar concentrations and $^{36}\text{Ar}/\text{C}$ ratios for several meteorite types. Units for $^{36}\text{Ar}/\text{C}$ are 10^{-8} cm^3 per g weight %, and are the typical analytical units reported for these elements. Each data point represents a separate meteorite except the two acid residue points for Murchison²⁷, two points for Chainpur LL3 \blacktriangle , and the averaged value for C3 chondrites. On this plot the Earth has a $^{36}\text{Ar}/\text{C}$ ratio of 473 and a ^{36}Ar concentration of 2.1 (ref. 2) and would plot far off the figure to the right. Meteorite data are taken from refs 7, 9, 10, 22, 25, 26.

lower by a factor of ~ 20 (as previously discussed²), C2s and C3s by a factor of ~ 14 , ureilites and unequilibrated chondrites by a factor of ~ 10 , and ordinary (LL) chondrites by a factor of ~ 45 . Ratios of Xe/C and Kr/C in meteorites are also lower than those ratios for the Earth by an order of magnitude or more. This conclusion arises from the fact that proportions of planetary Ar/Kr/Xe in various meteorite types are relatively constant, generally within a factor of 5 for Ar/Xe and a factor of 3 for Kr/Xe (refs 6–8), over a concentration range of three orders of magnitude. If anything ratios of Ar/Xe and Ar/Kr increase slightly with increasing ^{36}Ar concentration.

Neon in meteorites is more difficult to compare as it does not usually correlate with Ar. Neon in ordinary chondrites is almost entirely produced by cosmic ray interactions, and measurable amounts of planetary Ne has rarely been reported in these meteorites. Many individual meteorites representing essentially all meteorite types contain large quantities of neon implanted by the solar wind, and therefore are ill-suited for a comparison of planetary volatiles. Neon in ureilites is mainly produced by cosmic ray interactions, and the $^{20}\text{Ne}/^{36}\text{Ar}$ planetary ratio in ureilites is probably ≤ 0.01 (refs 7, 9). The unequilibrated chondrites also seem to contain little planetary Ne¹⁰. Even in carbonaceous chondrites the $^{20}\text{Ne}/^{36}\text{Ar}$ ratio varies by two orders of magnitude (~ 0.2 to 20) and indicates the presence of appreciable amounts of solar Ne in many samples⁷. The best estimate of the planetary $^{20}\text{Ne}/^{36}\text{Ar}$ mole ratio in carbonaceous chondrites is 0.28 (ref. 7), compared with the Earth value of 0.53 (ref. 2). With these values the $^{20}\text{Ne}/\text{C}$ ratio would be ~ 6 in carbonaceous chondrites and ~ 250 for the Earth. This is a difference of ~ 40 , which is essentially the value adopted by Turekian and Clark².

Available data, therefore, do not support the conclusion by Rasool and Le Sergeant¹ that the ratios of noble gases to carbon on Earth are much more similar to those of LL chondrites. The ³⁶Ar and C concentrations of LL chondrites, including the unequilibrated L3 chondrites, vary by factors of ~500 and ~22, respectively^{12, 13}. Thus the use of average or median concentrations from different populations instead of determinations for specific meteorites can be misleading. These authors reference the source of their noble gas and C data as two review papers. We surmise from their calculated ratios and from references given that they adopted a median C concentration of LL-chondrites¹² and an average noble gas abundance, which is also similar to a specific determination listed for Chainpur¹³. Chainpur is an LL chondrite which happens to be unequilibrated, and consequently has higher ³⁶Ar concentration and ³⁶Ar/C ratio than typical LL chondrites (Fig. 1). Various measured ³⁶Ar values for Chainpur also differ from one another and are lower by a factor of 4–20 than the LL chondrite ratio used by Rasool and Le Sergeant¹. The average ³⁶Ar/C of LL chondrites of petrographic grades 4–6 (Fig. 1) would be a factor of 45 lower than the ratio adopted by these authors. Similarly, the ²⁰Ne/C ratio adopted by Rasool and Le Sergeant for LL chondrites is much too high. As pointed out above, LL chondrites and unequilibrated chondrites (including Chainpur whose Ne content was apparently used by Rasool and Le Sergeant) rarely contain measurable amounts of planetary Ne (see, for example, refs 6, 10).

abundance pattern of volatiles on Earth could be derived from Ar-rich meteorites such as C1 chondrites by simple fractionation, as this would require greater loss of C relative to Ar, Kr, and Xe, and could be expected to fractionate Ar/Kr/Xe. The possibility of deriving the terrestrial volatiles from a component from which C had been selectively scavenged seems inconsistent with the relative nearness of the Earth to the Sun.

Rasool and Le Sergeant¹ also compared the relative abundances of volatile elements on Mars with their calculations for LL chondrites. Instead of normalising elemental ratios to C, for which the nonatmosphere inventory is unknown, they normalised to ³⁶Ar. They noted that the Kr/Ar and Xe/Ar ratios differed by only a factor of 3 between Mars volatiles and their LL chondrite values, and they used this similarity as evidence that volatiles on Mars were also introduced by a carrier similar to LL chondrites. But, such an argument based on the observed similarity in Kr/Ar and Xe/Ar ratios is trivial, because, as we summarised earlier, the Ar/Kr/Xe ratio is nearly constant for planetary gases in ordinary chondrites, unequilibrated chondrites, carbonaceous chondrites, ureilites, and the Earth. Thus, nearly constant Ar/Kr/Xe ratios would result no matter which of the above materials carried volatiles to Mars.

Another comparison is to consider the ³⁶Ar/N/C atom ratios in the atmospheres of Mars and Venus with these values for Earth and the meteorites (Table 1). The C and N abundances for meteorites and the Earth are measured and estimated values,

Table 1 Atom ratios of volatile elements in terrestrial planets and meteorites

Object	Ref.	N/C × 10 ⁻²	³⁶ Ar/N × 10 ⁻⁶	³⁶ Ar/C × 10 ⁻⁶	K/C	³⁶ Ar/K × 10 ⁻⁶
Earth*	2,21	4.6	5.5	0.25	1.8	6.3
Mars†	5	5.3	110	5.7	?	?
Venus‡	18	3.6	?	(200)‡	?	?
C1 chondrites§	7,22–24	3.7	0.33	0.012	0.0044	280
Ordinary chondrites	23–26	0.9–5	0.1–0.7	0.005	0.25	2.2

*K content of the Earth (minus the core) is taken as one-half chondritic²¹.

†Data for Mars and Venus are for atmospheres only. Reported data for Mars⁵ are assumed to be in volume %.

‡Total Ar/C ratio, where total Ar = ⁴⁰Ar + ³⁶Ar.

§N values used for C1s are recent measurements²², and are approximately a factor of 2 lower than previous values⁴.

||N abundances in ordinary chondrites show large variations^{22, 23, 25, 26}, and consequently only a range in N/C and ³⁶Ar/N is given.

What possible explanations exist for the observation that the Earth has considerably higher noble gas/C and noble gas/N ratios than known meteorite types (Fig. 1)? (1) Such ratios estimated for the whole Earth² may be incorrect. It is very unlikely that the abundances of Ar, Kr, and Xe for the Earth have been overestimated since the atmosphere contains the bulk of these gases, and the atmospheric abundances are known to a relatively high accuracy. The converse explanation, that the estimated abundances of C and N in the whole Earth² may be too low by a factor of 5–50, is perhaps possible. Essentially all of the estimated C in the Earth² is present as C in sediments (33 %) and ultramafic (mantle) rocks (~66%). Approximately 28 % of the estimated N in the Earth, on the other hand, is present in the atmosphere², and is known to a relatively high accuracy. (2) The Earth may have acquired its volatiles from a source unlike known meteorite types and one with higher Ar/C and Ar/N ratios. This possibility is plausible since the oxygen isotopic abundances of terrestrial materials is distinct from those of ordinary chondrites, carbonaceous chondrites, or ureilites¹¹. Unfortunately, Ar/C ratios are not known for differentiated objects (for example, achondrites, mesosiderites and the Moon) which have oxygen isotopic patterns analogous to the Earth¹², but which contain very little planetary Ar. (3) It seems unlikely that the relative

respectively, for the whole bodies, whereas the C and N abundances for Mars and Venus are the atmosphere inventories only. The ³⁶Ar/C and ³⁶Ar/N ratios for Mars are higher than those of Earth and meteorites by factors of ~20–4,000, which undoubtedly results because only a small fraction of the C and N acquired by Mars currently resides in its atmosphere⁵. Based on their assumption that volatiles on Mars have abundances like their calculated LL chondrite values, Rasool and Le Sergeant¹ estimated that ~3.5 % of the original C and ~6 % of the original N on Mars would be present in its atmosphere (assuming that all of the original ³⁶Ar is present in the atmosphere). If known meteorite types (Fig. 1) contributed the volatile elements to Mars, however, these values must be lowered, and only ~0.05 % of the original C and ~0.3 % of the original N on Mars would be present in its atmosphere. These values are consistent with the suggestion that large amounts of carbonates may reside in surface materials¹⁴, and with the estimate made from the ¹⁵N/¹⁴N ratio measured by Viking that ~10–150 times as much N has been lost to space from the atmosphere of Mars as has been retained¹⁵. It is interesting to note that the N/C ratio varies only little among the different objects listed in Table 1 in spite of variations in ³⁶Ar/N and ³⁶Ar/C by two orders of magnitude and more. Even the N/C ratio for the Mars atmosphere, which

apparently has lost large fractions of C and N by different mechanisms, is within a factor of 2 of the N/C values for the whole Earth and meteorites. The N/C ratio, therefore, is not likely to be diagnostic of any component which may have contributed volatiles to the terrestrial planets.

As discussed above, neither the relative abundances of volatile elements supplied to Mars, nor the fractions of original volatiles which now reside in its atmosphere can be precisely determined from the present data. This statement also applies to conclusions drawn from the measured $^{40}\text{Ar}/^{36}\text{Ar}$ ratios, as neither the $^{36}\text{Ar}/\text{K}$ or K/C ratios nor the fraction of ^{40}Ar degassed into the Martian atmosphere are known. It has been suggested that the high $^{40}\text{Ar}/^{36}\text{Ar}$ ratio for the Mars atmosphere ($2,750 \pm 500$ (ref. 5)) compared with the Earth's atmosphere (296) may be due to a higher K content and $\text{K}/^{36}\text{Ar}$ ratio for Mars compared with the Earth, or that ^{36}Ar has escaped from Mars^{16,17}. Fanale¹⁴ has suggested that both Earth and Mars received a K content similar to chondrites and that Mars received an ^{36}Ar content at least as high as Earth's. The K/C , K/N , $^{36}\text{Ar}/\text{C}$ and $^{36}\text{Ar}/\text{K}$ ratios for Earth and meteorites (Table 1) show considerable variation, however, and suggest that appreciable fractionation may have occurred in the $^{36}\text{Ar}/\text{K}$ ratio in the inner Solar System. Therefore this ratio cannot be assumed arbitrarily for Mars. The possibility of subsequent loss of ^{36}Ar from the Mars atmosphere^{16, 17}, and the uncertainty in the relation between early catastrophic degassing of ^{36}Ar and continuous degassing of ^{40}Ar (see, for example, ref. 14) add additional variables to any interpretation of the $^{40}\text{Ar}/^{36}\text{Ar}$ ratio of the Mars atmosphere.

It is also interesting to compare relative abundances of C, N and Ar recently determined in the atmosphere of Venus¹⁸ with those for Mars, meteorites and the Earth (Table 1). For the atmosphere of Venus the N/C ratio is similar to that of the whole Earth and meteorites, and the total amounts of N_2 and Ar in the Venus atmosphere are similar to total amounts in the Earth's atmosphere¹⁸. These observations suggest that large fractions of the C, N and ^{36}Ar on Venus may reside in its atmosphere. As for Mars, however, both the relative abundances of volatiles supplied to Venus and the fractions of original volatile elements which now reside in the atmosphere are unknown. If we assume that volatiles supplied to Venus had $^{36}\text{Ar}/\text{C}$ and $^{36}\text{Ar}/\text{N}$ ratios like the Earth's and that these ratios in the atmosphere of Venus reflect the whole planet inventory, we can calculate $^{40}\text{Ar}/^{36}\text{Ar}$ ratios for Venus of 800 and 1010, respectively, by the following formula and its equivalent for Ar/N :

$$[^{36}\text{Ar}/\text{C}]_{\text{Earth}} + [^{40}\text{Ar}/\text{C}]_{\text{Venus}} = [\text{total Ar}/\text{C}]_{\text{Venus}}$$

Similarly, if we assume volatiles supplied to Venus had $^{36}\text{Ar}/\text{C}$ and $^{36}\text{Ar}/\text{N}$ ratios like CI chondrites, calculated $^{40}\text{Ar}/^{36}\text{Ar}$ ratios for Venus are 16,666 and 16,847 respectively. Calculated $^{40}\text{Ar}/^{36}\text{Ar}$ ratios of ~ 900 would suggest that either Venus has a $\text{K}/^{36}\text{Ar}$ ratio ~ 3 times that of the Earth or that radiogenic ^{40}Ar on Venus has been ~ 3 times more efficiently degassed into the atmosphere. The latter explanation seems to be consistent with the measured high surface temperature on Venus¹⁹ and the recent radar observations of apparent large volcanoes²⁰. Calculated $^{40}\text{Ar}/^{36}\text{Ar}$ ratios of $\sim 16 \times 10^3$, however, would imply either a $\text{K}/^{36}\text{Ar}$ ratio or a ^{40}Ar degassing fraction higher by a factor of ~ 57 on Venus compared to the Earth. It has been estimated that 7–90% of the Earth's total ^{40}Ar (depending on the K content adopted) has been degassed into the atmosphere^{2, 14, 21}. Therefore, to assume that volatiles on Venus have relative abundances like CI chondrites would also require higher $\text{K}/^{36}\text{Ar}$ ratios than either the Earth or CI chondrites (Table 1). The simpler explanation is that volatiles accreted by Venus had relative abundances similar to those on Earth, and that Venus has degassed a higher fraction of its ^{40}Ar . This explanation, however, depends on the assumption that the

$^{36}\text{Ar}/\text{N}/\text{C}$ ratios of the atmosphere of Venus are essentially identical to the whole planet inventory, which may not be true.

Limits to palaeogravity since the late Precambrian

HYPOTHESES involving substantial changes in Earth radius over geological time can be tested by measuring palaeogravity at, or near, the Earth's surface. The measurements are obtained by comparing the pressure–temperature conditions in the upper mantle, disclosed by kimberlite nodules of known age, with the computed pressure–temperature conditions for that time¹. Recently published data for six groups of kimberlites, the earliest from the late Precambrian, are analysed here.

Temperature of formation of pyroxene–garnet bearing nodules can be determined by the diopside geothermometer^{2, 3}. Pressure can be obtained from the alumina content of enstatite⁴. An adjustment of -8×10^8 Pa has been applied to all pressures not corrected for presence of calcium and iron in the system^{5, 6}. An envelope drawn tightly around points on the pressure–temperature plot for each kimberlite suite has been used to measure the uncertainty in the pressure determinations (Fig. 1). Envelopes are elongated, their gradients at relatively low pressures similar to those expected for the palaeogeotherm. Gradients at relatively higher pressures, however, are sometimes steeper. Such 'inflected' geotherms probably indicate some kind of thermal instability in the mantle and so separate calculations have been made for the low and high pressure nodules in each kimberlite suite.

The pressure–temperature conditions in the upper mantle beneath stable continents at the present time have been computed by several workers from measured heat flow and plausible arrangements of heat producing elements and conductivities^{7–9}. The two geotherms plotted in Fig. 1 represent extreme conditions—average continental lithosphere with heat flux 1.0 hfu (ref. 7) and lithosphere beneath Montana with heat flux

Fig. 1 Pressure-temperature conditions in the upper mantle deduced from ultramafic nodules in six kimberlite suites; ages in Myr BP. Dotted lines are limits to pressure and temperature beneath stable continents at present.

1.2 hfu (ref. 9). Heat production in the past was greater than now, however. For example, 1,100 Myr ago it was 1.2 times the present value¹⁰ and assuming thermal equilibrium the geothermal gradient would have been correspondingly steeper. For each kimberlite suite, therefore, a separate geotherm has been computed (not shown in Fig. 1) assuming a linear decline in heat production over 1,100 Myr.

A maximum limit to palaeogravity can be obtained by dividing the greatest pressure deduced from mineral chemistry ($P_m + p_m$) by the least pressure from the geotherm ($P_g - p_g$), both at the same arbitrarily chosen temperature T_m . Reversing the procedure gives a minimum limit. So

$$g_{max} = [(P_m + p_m)/(P_g - p_g)]g_0$$

and

$$g_{min} = [(P_m - p_m)/(P_g + p_g)]g_0$$

where P is mean pressure, p the uncertainty and g_0 the present value of gravity. The term involving the gradient of the geotherm formerly used¹ may be neglected. Limits derived from the above equations are given in Table 1. A reason for calculating limits rather than mean values for palaeogravity is

the difficulty of selecting a standard geotherm for all continental lithosphere. The difference between pressure-temperature plots for different kimberlites in southern Africa may lie partly in regional variations in the geotherm¹¹. Another reason is the possibility of systematic errors of 10^8 to 10^9 Pa in the pressure estimates derived from mineral chemistry. Nevertheless, the limits are probably more reliable than those derived by using a similar technique on upper mantle peridotites or metamorphic mineralogy¹ for which the geothermal regimes are even more uncertain.

Fig. 2 Limits to palaeogravity over the period 100 Myr to 1,115 Myr. Lower limits come from the kimberlite data in Fig. 1. Upper limits are determined from metamorphic mineralogy (see text). Present gravity at the Earth's surface is g_0 .

The new results show that gravity since the late Precambrian could never have been much less than at present. The lower limit from the Premier Mine is particularly significant; it is fractionally greater than unity and thus lends no support to the most recent version of the contracting Earth hypothesis¹². This hypothesis requires virtually instantaneous core formation by phase change about 2,500 Myr ago, followed by a gradual contraction of Earth radius from 6,671 km (which implies $g = 0.9 g_0$) to the present value of 6,371 km.

The upper limits to palaeogravity obtained are of little use. A more stringent upper limit for the Phanerozoic ($g < 1.4 g_0$) from the non-occurrence of lawsonite in deep sedimentary

Table 1 Limits to palaeogravity derived from the envelopes in Fig. 1

Kimberlite suite	Ref.	Age (Myr)	P_m (10^8 Pa)	p_m (10^8 Pa)	P_g (10^8 Pa)	p_g (10^8 Pa)	$\frac{g_{max}}{g_0}$	$\frac{g_{min}}{g_0}$
Premier Mine	19	1,115	39.0	3.0	24.5	10.0	2.9	1.0
South Africa			55.5	1.5	38.0	15.0	2.5	1.0
Sloan II	20	400	56.7	7.3	42.0	12.0	2.1	0.9
USA								
Udachnaya	21	300	37.5	6.5	27.5	9.0	2.4	0.8
USSR			56.5	6.5	43.0	12.0	2.0	0.9
Kimberley	3,22,23	90	39.7	3.7	31.0	11.0	2.2	0.9
South Africa			52.0	3.0	57.0	14.0	1.3	0.7
South West	24	70	38.0	3.0	35.5	9.5	1.6	0.8
Africa			37.0	3.0	48.0	10.0	1.1	0.6
Montana	25	46	36.5	0.5	32.0	8.0	1.5	0.9
USA			47.0	1.0	59.0	13.5	1.1	0.6

The top line of data for each kimberlite suite relates to low pressures and temperatures and is probably the more reliable.

basins, has already been published¹. The limit rises to 2.0 g_0 at the end of the Precambrian when allowance is made for increased continental heat production. It compares with a Proterozoic maximum of 2.1 g_0 , using a compromise aluminium silicate triple point¹³ ($P_m = 4.8 \times 10^8$ Pa, $p_m = 1 \times 10^8$ Pa, $T_m = 575^\circ\text{C}$, $P_g = P_m$, $p_g = 2.0 \times 10^8$ Pa) and the equations given above. These upper limits flatly contradict rapid Earth expansion models¹⁴⁻¹⁶ unless mass increases with radius. Rapid expansion models require Earth radius to have been 4,500 km in the Carboniferous, 300 Myr ago, which gives $g = 2 g_0$. Slow Earth expansion^{17, 18} is still possible, however.

Phytoplankton biology of a thermal front in the Celtic Sea

SEASONAL thermal fronts which occur in coastal waters are typified by sharp lateral gradients of temperature at the sea surface resulting from a surface outcropping of the thermocline. The frontal regions are areas of considerable physical and biological activity; in the case of the fronts in the Celtic and Irish Seas this increase in biological activity is reflected in marked increases of chlorophyll *a* at the sea surface¹. Considerable data on the spatial distribution of physical and chemical characteristics of the water and chlorophyll *a* concentrations in the vicinity of these and other fronts are now available²⁻⁵. But, few observations have been made either on the temporal variability of these characteristics or on the more detailed distribution of phytoplankton productivity. During a survey of the Celtic Sea in September 1976 we made consecutive crossings of the frontal region in order to investigate the small-scale distributions of chlorophyll *a* and primary productivity and their interrelationships with selected physical and chemical variables.

Temperature, salinity and concentrations of dissolved silicate and chlorophyll *a* were recorded continuously along the ship's track from water pumped through a port in the ship's hull at a depth of 2 m (ref. 2). Single observations of productivity were determined from phytoplankton samples also taken from this source. The productivity was estimated by the standard ¹⁴C uptake method⁶, samples being incubated for 3 h under a light intensity of 6 kl. The samples were cooled by pumping surface seawater through the incubator. During the first two transects of

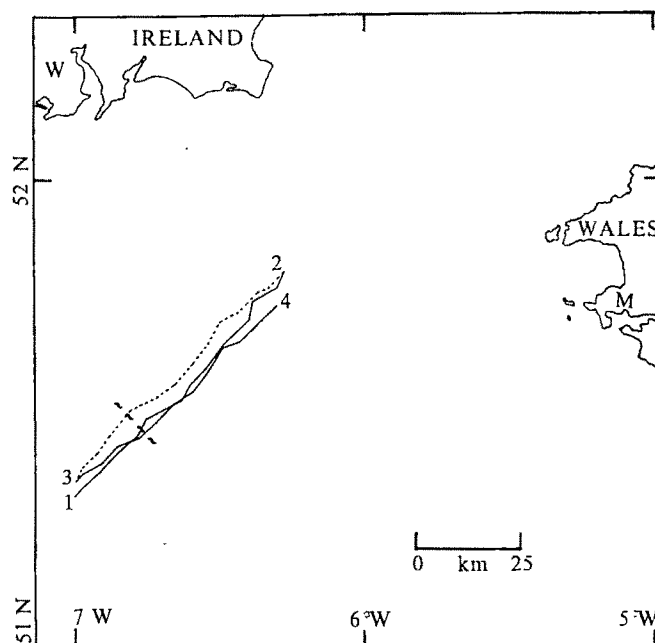

Fig. 1 Location of transects of Celtic Sea thermal front on 8 September 1976. ~~, Approximate position of main frontal boundary. Position 1, start of first transect; position 2, end of first transect and start of second; position 3, end of second transect and start of third; position 4, end of third transect. W, Waterford; M, Milford Haven.

the front, marked increases in productivity and chlorophyll were found to be associated with zones of increased lateral temperature gradient at the sea surface. In the third and final transect, however, this association between the physical and biological properties was masked by the development of sharp local increases in the magnitude of the biological characteristics. These local increases seemed to result from the greater degree of wind mixing experienced on this transect.

Continuous on-line analysis of the physical properties and the dissolved constituents along a transect approximately parallel to the tidal stream (Fig. 1) provided a detailed characterisation of the frontal structure. The essential physical features of the initial and final traverses are summarised in Figs 2 and 3 respectively, and the mean characteristics of the identified water types are listed in Table 1.

In the initial transect, waters exhibiting uniform characteristics typical of supra-thermocline waters in this region (type A) were terminated by a sharp thermal gradient ($\sim 1^\circ\text{C mile}^{-1}$) and chemogradient ($\sim 75 \mu\text{g Si l}^{-1} \text{ mile}^{-1}$). Adjacent to the front a pronounced temperature minimum (the lowest recorded along the transect), with associated salinity minimum and nutrient maxima, indicated a narrow band of water with a significant upwelled component⁷. Between the main frontal features and the major body of cool water (C) lay a lens of warm water (B) bounded by minor but distinct thermal gradients, suggesting a zone of less vigorous mixing in the frontal circulation leading to localised surface heating.

A gradual deterioration in weather conditions accompanied subsequent transects. The essential hydrographic features observed in transect 1 were also evident in the second transect, although in general the boundaries were less well demarcated. Despite the

Table 1 Mean characteristics of the water types depicted in Figs 2 and 3

Water type	Salinity (‰)	Temperature (°C)	Silicate concentration ($\mu\text{g l}^{-1}$)
A (Fig. 2)	35.10	17.50	26
B	34.88	15.70	165
C	34.90	15.25	185
A (Fig. 3)	35.05	17.65	20
D	35.15	16.70	125
E	34.85	15.80	200
F	34.90	15.20	220

increase in the wind-induced mixing, in the final transect the major thermal discontinuity, together with its boundaries of warm and upwelled water, was still prominent. Three additional distinct water types (D, E, F), demarcated by thermal, halo- and chemo- gradients, were evident in a direction away from the major discontinuity. Although the average temperature and salinity of water types E and F were similar to those of the corresponding water types B and C in the previous two transects, average silicate concentrations had increased significantly.

The chlorophyll *a* and productivity records associated with these transects are illustrated. Reference to Fig. 2 clearly demonstrates that the complementation of waters of inherently different properties induces fertility¹. Low chlorophyll *a* concentrations prevailed throughout the stratified waters on the warm side of the major thermal boundary and within the main water bodies of B and C, while chlorophyll peaks occurred at the thermal discontinuities. The fertilisation effect is further emphasised by the magnitude of the chlorophyll peaks at the discontinuities. Low chlorophyll *a* concentrations in the central body of the upwelled water increased towards the bounding thermal fronts. The increase in a direction towards the major temperature gradient was significantly less marked, however, reflecting the reduced degree of mixing between the contrasting water types adjacent to the major lateral density gradient. Maximum chlorophyll *a* concentrations occurred in the minor density gradient between water types B and C where a greater degree of lateral mixing was possible.

In the final transect chlorophyll *a* concentrations exhibited a marked spatial variability (Fig. 3). In contrast to the initial

Fig. 2 The physical structure, chlorophyll *a* and productivity records observed during transect 1 across the front 0530 to 0930 8 September 1976. Abscissa denotes distance along the transect. Solid line represents productivity; dotted line represents chlorophyll concentration. Areas of sharp temperature gradient (■), the major front (m.f.), the upwelling zone (↑) and distinct water types are depicted.

transect, high concentrations not only occurred at the boundaries of the various water types, but also within them. Chlorophyll patches, approximately 0.75 miles across and containing up to $15 \mu\text{g l}^{-1}$, existed within water type E and persisted across the discontinuity into water type F. The chlorophyll patchiness coincided with noise on the temperature record indicating a causal relationship between patchiness and wind induced mixing within the bounds of the thermal discontinuities.

The productivity data, based on discrete samples, were less comprehensive. Nevertheless, the initial transect, which was preceded by a period of calm, depicted a distinct pattern of biological activity associated with the main physical features of the frontal system. A positive correlation between productivity and chlorophyll was clearly evident, with increases in productivity being particularly marked at the discontinuities. This relationship is associated with a later stage of development in frontal dynamics

Fig. 3 The physical structure, chlorophyll *a* and productivity records observed during transect 3 across the front 1330 to 1720 8 September 1976. Abscissa denotes distance along the transect. Solid line represents productivity; dotted line represents chlorophyll concentration. Areas of sharp temperature gradient (■), the major front (m.f.), the upwelling zone (↑) and distinct water types are depicted.

during a period of stability. Sufficient time has elapsed for increases in productivity arising from the admixing of the contrasting water types to be reflected in an increase in phytoplankton stock, resulting in the observed positive correlation. For this condition to occur, it is clear that sufficient nutrients must remain in the mixed water in order to sustain a high level of production; also increases in phytoplankton must be in excess of losses from advection, diffusion and grazing. The corresponding early stage in the development of the dynamics will be represented by inverse correlations between these two characteristics: insufficient time will have elapsed for an increase in productivity resulting from admixing of water to be reflected in increases of the stock of phytoplankton.

In subsequent transects, wind induced mixing led to a rapidly evolving pattern of phytoplankton productivity and growth, resulting in a marked increase in the spatial variability of these parameters. The magnitude of the transient features of the biological characteristics was comparable to those observed earlier at the discontinuities. The spatial variability was especially evident in the cool waters of the frontal region in the final transect where an inverse relationship between productivity and chlorophyll was apparent. But, the increased mixing and spatial variability indicate that this relationship was not a reversion to an early stage in the sequential development of phytoplankton dynamics in a frontal region. Further support for this contention is available in the rate of evolution of the chlorophyll patches. Division time of phytoplankton in the sea averages 24 h^8 , whereas the chlorophyll transects showed at times a doubling of concentration within 6 h. The time scale of our observations therefore suggests that the development of the marked spatial variability in chlorophyll distribution was predominantly a consequence of physical aggregation and the outcropping of sub-surface concentrations of phytoplankton.

We thank the Captain and crew of the R.V. Prince Madog for their cooperation and Mr P. Johnston for his assistance with the productivity estimations.

A photoaffinity-labelled insect sex pheromone for the moth *Antheraea polyphemus*

SINCE the isolation of the first insect sex pheromone, bombykol, from the female silkworm *Bombyx mori*¹ and its full identification by synthesis as (10E, 12Z)-10,12-hexadecadienol^{2,3}, the number of characterised pheromones has increased dramatically⁴⁻⁷. The basic question of pheromone-receptor interactions remain unanswered, however. To devise a method which could be used to study such problems, it was necessary to modify the natural pheromone in such a way as to specifically label the binding site of its chemoreceptor cell. We chose to convert the acetate group, a common feature in Lepidoteran pheromones⁴⁻⁷, into a diazoacetate derivative. Information about the active site of the pheromone receptor cell can then be obtained by reacting it irreversibly with a carbene derived from the diazoacetate group. In this procedure, the modified pheromone is radioactively labelled, and since the carbene is generated photolytically, the process is called photoaffinity labelling^{8,9}. We have used electrophysiological techniques as a very sensitive and rapid bioassay method to check the activity of the modified pheromone. We recorded the responses from single receptor cells and evaluated the changes in receptor potential and nerve impulses activity accompanying exposure of the antennae to a stream of pheromone¹⁰⁻¹². We describe here experiments showing that the diazoacetyl derivative of the pheromone acetate (VII) meets the requirements of a photoaffinity label for the study of the receptor.

Fig. 1 Synthesis of the pheromone (6E, 11Z)-6, 11-hexadecadienyl acetate (VII) and its diazoacetate.

Fig. 2 Electrophysiological recordings from a single olfactory hair which is innervated by two receptor cells. *a*, One cell produces small nerve impulses and responds to (6E, 11Z)-6, 11-hexadecadienyl aldehyde 10^{-3} μg . *b*, The other cell fires large nerve impulses and is sensitive to (6E, 11Z)-6, 11-hexadecadienyl acetate 10^{-3} μg . *c*, The photoaffinity label (6E, 11Z)-6, 11-diazoacetate (DAC) at 10^{-2} μg excites only the 'acetate cell' (large impulses). The stimulus strength is given as the amount of each compound on a 1-cm² filter paper. *d*, The 'aldehyde cell' (small impulses) responds after irradiation of DAC with ultraviolet light (256 nm, 1 min on each side of the filter paper). The 'acetate cell' fires only very few impulses. Probably, most of the diazoacetate is converted into the aldehyde. *a-d*, Each response is given as a d.c. recording (lower traces) showing the receptor potential with superimposed nerve impulses, and as a.c. recording (upper trace) showing the enlarged nerve impulses. *e*, Response of a thermistor indicating the air-stream velocity at the antenna. The 5mV calibration refers to d.c. signals.

The sex attractants of the wild silkworm *Antheraea polyphemus* (Cramer), a saturniid distributed throughout North America, have been characterised as (6E, 11Z)-6,11-hexadecadienyl acetate VII and its corresponding aldehyde by microchemical reactions, single cell recordings, and synthesis¹³. A 9:1 mixture of the acetate and aldehyde elicited strongest attraction to wild males in field tests.

The pheromones and derivatives were synthesised as outlined in Fig. 1. A Wittig reaction between acetoxy aldehyde (I) and tetrahydropyranyl (THP) derivative II of bromohexanol in ether -45°C for 80 min, followed by addition of ethanol, led to concomitant deacetylation to give a mixture of 6E-alcohol III and the 6Z isomer. The mixture was oxidised with pyridinium chlorochromate¹⁴ to the aldehydes which were separated by preparative liquid chromatography (LC) (Waters Prep LC500, 11% ether in hexane) using a silica gel column impregnated with 10% silver nitrate¹⁵. A second Wittig reaction between 6E aldehyde IV and bromopentane in ether at -45°C for 80 min followed by quenching with water, gave a 60:40 mixture of 11Z (V) and 11E THP ethers which were separated by preparative thin layer chromatography (TLC) on silver nitrate impregnated plates. Hydrolysis of the desired 6E, 11Z-THP ether (6% overall yield from acetate I) gave the alcohol VI which was

acetylated to pheromone VII. Reaction of alcohol VI with the *p*-toluenesulphonylhydrazide of glyoxylic acid chloride and triethylamine gave the diazoacetate VIII, with ultraviolet absorption bands (in hexane) of: 243 nm (10,000), 225 (8,900), 203 (12,700). Purity of final products and double bond isomers, except for the diazoacetate, was checked by gas chromatography.

Photolysis of the diazo group in diazo esters, for example VIII, affords the divalent carbene IX which is known to insert into nearby C-H, O-H, and N-H bonds^{8,9,16,17}. The diazoacetate VIII was relatively stable to sunlight; only 23% underwent photolysis when 60 µg in 3 ml hexane was exposed to sunlight for 60 min. But the same amount was totally photolysed after 10 s in a 254 nm Rayonet with 16 tubes.

It is now well-known that slight modifications in the structures of pheromones, for example, isomerism of double bonds or, especially, modification of terminal functions, lead to a drastic (10^{-1} to 10^{-3}) decrease in activity; also it is known that with certain insects the isomeric ratio of *Z/E* plays a critical part in pheromone reception^{18,19}. It was therefore gratifying to find that, when the 6*E*,11*Z*-diazoacetate VIII was submitted to electrophysiological tests (Fig. 2), it retained 10% of the activity of the natural pheromone VII and it elicited response of the acetate receptor cell dendrites but not of the aldehyde-sensitive cells. The 10% retention of activity has provided the incentive for further radiolabelled photoaffinity studies and detection of pheromone receptors.

Furthermore, electrophysiological experiments showed that neither *Antheraea roylei* nor *Bombyx mori* responded to the diazoacetate VIII (or acetate VII), thus indicating that the diazoacetate is not reacting with the *polyphemus* receptor cell in a random nonspecific manner. Interestingly, when a 1 cm² filter paper treated with 10^{-2} or 10^{-1} µg of the diazoacetate was irradiated for 1 min by an ultraviolet lamp, the aldehyde-sensitive cells responded but the acetate-sensitive cells did not.

It is possible that, in these conditions, the carbene undergoes a Wolff rearrangement to a ketene^{17,20} and that the ketene is further photolysed to the aldehyde²¹, the minor component¹³ of the natural pheromone.

Our results show that the diazoacetate equivalent of natural pheromones containing acetate groups; coupled with electrophysiological tests, could offer a promising lead to the study of pheromone receptors in insects.

Infection of human pancreatic beta cell cultures with mumps virus

THE development of a diabetes-like syndrome in virus-infected animals, particularly in certain strains of mice infected with the M-variant of encephalomyocarditis (EMC) virus has recently been demonstrated^{1,2}. The possibility that viruses might also cause diabetes mellitus in humans, particularly in juveniles, has been suggested periodically since the turn of the century^{3–6}. The evidence, however, is largely circumstantial and comes from case reports showing a temporal relationship between the onset of certain viral infections, particularly mumps, and the subsequent development of diabetes. Although it has been known for some time that pancreatitis may be a complication of mumps^{7–10}, specific involvement of the beta cells has never been demonstrated. Since it is not feasible to obtain pancreatic biopsies during the course of viral infections, we initiated experiments to determine if human pancreatic beta cells grown in culture were susceptible to mumps virus. We have used a double-label antibody technique, using fluorescein labelled anti-mumps antibody and rhodamine labelled anti-insulin antibody, and we show here for the first time that human beta cells can be infected with mumps virus.

Human pancreas was obtained at autopsy, usually within 12 h after death, from subjects aged 3 d to 46 yr, from the Division of Transplantation Surgery, Naval Medical Research Institute, Bethesda, and from the Department of Pathology, Children's Hospital, District of Columbia. Specimens were minced, washed in phosphate-buffered saline (PBS) and digested at 37 °C in PBS containing 0.1% collagenase (202 units mg⁻¹), 0.1% trypsin and 1.0% bovine albumin. Pilot experiments with 15 human and 50 non-human primate pancreas showed that this treatment was necessary to prevent gelatinous aggregation of the dispersed cells. The cells then were washed in PBS and resuspended in Ficoll-PBS (23.7% w/v) at a concentration of 2×10^7 cells ml⁻¹. A discontinuous Ficoll-PBS gradient was prepared with layers of 21.0%, 23.7% (containing cells) and 25.0%, and centrifuged at 350g at 4 °C for 20 min. The cells at the interface of the 23.7% and 25.0% layers were then decanted and cultured on glass coverslips in MPNL65/C medium¹¹ with 10% heat-inactivated foetal bovine serum. Immunofluorescent staining of cells collected on a gradient with anti-insulin antibody demonstrated that approximately 1–5% of the cells were beta cells; a 10-fold enrichment over cells not passed through the gradient.

The ABC strain of mumps virus (from Dr Thomas Flanagan) was grown in African green monkey kidney cell line MA-134 (Microbiological Associates). Pancreatic cells that were in culture for 3–4 d were infected with mumps at a virus to total cells ratio of approximately 1.0. At appropriate intervals, coverslips were fixed for 10 min in acetone and stored at 4 °C until reacted with labelled antibodies.

Antiserum to bovine insulin prepared in guinea pigs (from Dr Peter F. Wright) was labelled with tetramethyl rhodamine isothiocyanate (TRITC; Baltimore Biological Laboratories)¹². The specificity of this reagent was determined by reaction of 6-µm cryostat-sectioned, acetone-fixed human pancreas. Only insulin-containing beta cells in the islets stained bright orange (Fig. 1a). The surrounding

Fig. 1 *a*, Section of human pancreas stained with TRITC-labelled anti-insulin antibody. The photograph was taken with rhodamine filters. *b*, Mumps-infected MA-134 cells stained with FITC-labelled anti-mumps antibody (fluorescein filters). *c*, *e*, *g*, *i*, Human pancreatic cultures infected with mumps virus, stained with TRITC-labelled anti-insulin and FITC-labelled anti-mumps antibodies (rhodamine filters). *d*, *f*, *h*, *j*, Same cultures as above, but photographs taken with fluorescein filters. Magnifications: *b-h*, $\times 2,000$; *a*, *i*, *j*, $\times 800$.

acinar cells did not stain. Absorption of the labelled antibody with purified bovine insulin completely blocked staining (data not shown).

Antiserum to mumps virus, prepared in guinea pigs and labelled with fluorescein isothiocyanate (FITC), was purchased from Microbiological Associates. The specificity of the antiserum was demonstrated by reacting it with mumps-infected MA-134 cells. Mumps antigens stained brilliant apple-green, showed an irregular distribution in the cytoplasm, and seemed more globular than insulin antigens (Fig. 1*b*). Uninfected cells did not stain.

To identify mumps-infected beta cells, coverslips that had been prepared from infected and uninfected pancreatic cultures were stained first with TRITC-labelled anti-insulin antibody, washed and then stained with FITC-labelled anti-mumps antibody. When the order of staining was reversed the rhodamine intensity was slightly diminished, but specificity was not changed.

Coverslips were examined with a Standard Universal Zeiss Microscope illuminated by an HBO 200 mercury lamp. For detection of FITC-labelled anti-mumps antibody, KP490 and

BG12 excitation filters and an LP528 barrier filter were used. For detection of TRITC-labelled anti-insulin antibody, a BP546/9 excitation filter and an LP590 barrier filter were used. Double-stained cells were identified by screening sections first with the rhodamine filters and then with the fluorescein filters.

Human pancreatic cultures were infected with mumps and at various times thereafter stained by the double-label antibody technique. Figure 1*c* and *d* shows a single cell containing both mumps antigen and insulin. When the rhodamine filters were used to examine the cell (Fig. 1*c*), a diffuse homogeneous orange colour, distributed throughout the cytoplasm, was observed. When the same cell (Fig. 1*d*) was examined using fluorescein filters, a brilliant apple-green colour was seen in the cytoplasm. Neither mumps nor insulin was detected in the nucleus. Similarly, the cell in Fig. 1*e* was identified as a beta cell by its orange appearance when viewed with rhodamine filters and as a mumps-infected cell by its green appearance (Fig. 1*f*) when viewed with fluorescein filters. The irregular distribution and globular appearance of the mumps antigen

is very similar to that seen in infected MA-134 cells (Fig. 1b). In addition, Fig. 1f shows mumps antigens in adjacent cells, but the lack of fluorescence in the corresponding positions in Fig. 1e, when rhodamine filters were used, indicates that these cells do not contain insulin. This is even more apparent by contrasting Fig. 1g and h, which show a single beta cell and a portion of a second beta cell (1g) infected with mumps (h) and several non-insulin-containing epithelioid cells also infected with mumps (h). Thus, by use of the double-label antibody technique it is possible to identify infected, insulin-containing, beta cells in a population consisting predominantly of infected non-beta cells. This technique also can be used to detect uninfected beta cells in a field of infected, non-insulin-containing cells. When the rhodamine filters were used, the two cells in Fig. 1i stained bright orange, indicating that they were beta cells; the lack of colour in corresponding positions in Fig. 1j, when the fluorescein filters were used, showed that these beta cells were not infected with mumps. The presence of green fluorescence in the lower left corner of Fig. 1j showed that this cell was infected with mumps, but the lack of orange fluorescence in the corresponding position in Fig. 1i indicated that it was not a beta cell.

To study in more detail the effect of mumps virus replication on pancreatic cell survival, cultures prepared from a single human pancreas were examined daily for 6 d. The percentage of beta cells and non-beta cells that became infected was evaluated by the double-label antibody technique. The data in Fig. 2 show that at 2 d after infection, 32% of the beta cells and 50% of the non-beta cells had become infected with mumps. At 3 d, approximately equal proportions (75%) of beta and non-beta cells

were infected. Virus titres in the cultures increased from $10^{1.2}$ plaque-forming units (PFU) per culture at 24 h after infection to $10^{5.8}$ PFU at 72 h. The infectious titre declined over the next 3 d. The ratio of the number of beta cells in infected cultures to the number of beta cells in uninfected cultures declined from 1.0 at 24 h after infection to 0.1 at 6 d after infection. The highly lytic nature of the mumps infection points to beta cell death as the most likely explanation for this decrease rather than virus-induced degranulation. A similar decline in the number of non-insulin-containing cells in infected cultures also was observed.

In all, pancreatic cultures from seven subjects were examined for their susceptibility to mumps virus. Patients were of both sexes, and ranged in age from 3 d to 46 yr. The proportion of beta cells in these cultures, determined by staining with TRITC-labelled anti-insulin antibody, ranged from 1–5%. By the third day after infection, 60–90% of the beta cells in these cultures contained mumps antigens. Similarly, 60–95% of the non-insulin containing cells in the same cultures also contained mumps antigens.

By use of the double-label antibody technique, we have shown that human beta cells are susceptible to mumps virus. Moreover, by this technique we have shown that it is possible to identify infected beta cells in a population which contains predominantly (>95%) non-beta cells. In our experiments, beta cells from all seven human pancreas examined seemed to be susceptible to infection with the ABC strain of mumps. We have been able to show that beta cells from African green and rhesus monkeys also are susceptible to *in vitro* infection with mumps virus (data not shown). It must be emphasised, however, that these experiments by no means prove that mumps can produce diabetes. It remains to be determined whether the *in vitro* conditions may have altered the beta cells in such a way as to make them susceptible to a variety of viruses to which they would not have been susceptible *in vivo*. If future experiments show that beta cells grown in culture are restrictive to the replication of certain viruses, but allow the replication of other viruses, then this *in vitro* approach might serve as a useful screening technique for identifying viruses that have a tropism for human pancreatic beta cells and therefore have diabetogenic potential.

Because of the near universal prevalence of mumps, it is clear that if mumps virus is capable of infecting beta cells *in vivo* and producing diabetes, it must do so only in very special circumstances. That is, a particular variant of mumps virus must be involved and/or the individual who develops mumps must have an unusual, possibly genetically determined, susceptibility to the virus. Indirect evidence that a variant of mumps might be involved comes from epidemiologic studies which showed an increased incidence of juvenile diabetes following only certain mumps epidemics^{4–6}. It may be relevant that in mice, only the M-variant of the EMC virus group produces diabetes and the degree of diabetes varies with the passage history of the virus^{1,2}. Host defence mechanisms may also play an important part in determining whether an infected individual develops diabetes. Ordinarily, these host defences prevent the spread of the virus from the salivary glands to the pancreas. If, however, in unusual circumstances, mumps virus reaches the pancreas, the virus may infect and destroy beta cells. Whether such an infected individual develops diabetes may depend on the number of beta cells destroyed.

Finally, it is known that genetically determined host factors control the susceptibility of murine beta cells to EMC virus infection¹. In humans, the frequency of certain HLA antigens (for example, B8, BW15) is several times greater in insulin-dependent juvenile diabetics than the general population^{13,16}. By use of the double-label antibody technique, it might now be possible to determine if beta

Prostaglandins in urine of foetal lambs

ALTHOUGH prostaglandins of the E and F series have been measured in amniotic fluid from several species¹⁻³ their principal site of synthesis remains uncertain. In man, for example, the decidua^{4,5} foetal membranes^{6,7} and myometrium⁸ have all been shown to synthesise prostaglandins *in vitro* and each may contribute to the prostaglandin composition of amniotic fluid. The foetal lung and kidneys secrete considerable volumes of fluid into the amniotic sac^{9,10} and hence may also contribute to the prostaglandin content of amniotic fluid. The levels of prostaglandins in foetal tracheal fluid have been shown to be much lower than those in amniotic fluid¹¹ and it was suggested that foetal urine is a more likely source of amniotic fluid prostaglandins. The foetal kidney is capable of synthesising prostaglandins¹² and there is a growing body of evidence that prostaglandins are intimately involved in renal function¹³⁻¹⁵. We have, therefore, measured the concentrations of PGE, PGF and 13, 14-dihydro-15-keto-prostaglandin F (PGFM) in foetal urine during late pregnancy in sheep and have further determined the osmolality, Na⁺ and K⁺ concentrations of foetal urine and plasma. The concentrations of prostaglandins measured in foetal urine were similar to amniotic fluid levels but significantly greater than those previously reported in plasma and tracheal fluid suggesting that the kidney is a major source of amniotic fluid prostaglandins. The excretions of prostaglandins were related to the rate of urine flow; the excretions of PGF and PGFM were correlated with osmolar and solute-free water clearances and Na⁺ excretion, whereas excretion of PGE was related only to the clearance of solute-free water. Prostaglandins may thus contribute substantially to renal function and volume homeostasis in foetal life.

Four cross-bred sheep were used in this study. At laparotomy between 115 and 120 d of gestation catheters were implanted into a foetal femoral artery, tarsal vein and amniotic sac and also into the foetal urinary bladder using procedures described previously^{16,17}. Daily samples (2 ml) were taken from the femoral artery for measurements of P_{O_2} , P_{CO_2} , pH and haematocrit in whole blood and osmolality, Na⁺ and K⁺ concentrations in plasma. Foetal urine was collected for periods of 1-4 h by placing the free end of the bladder catheter 30 cm below the level of the foetus and allowing urine to drain by gravity. Plasma and urine samples were frozen immediately after collection and stored at -20 °C until analysis. P_{O_2} , P_{CO_2} and pH were measured using a Radiometer blood gas analyser. Osmolalities

Table 1 Prostaglandins in urine from four foetal lambs at 124-144 d gestation

	PGE	PGF	PGFM
Concentration (ng ml ⁻¹)	4.59±0.61 (18)	1.96±0.41* (23)	2.64±0.19† (23)
Excretion (ng min ⁻¹)	2.36±0.31 (18)	0.98±0.19* (23)	1.36±0.18† (23)

Values are means ± s.e.; figures in parenthesis are no. of samples.

* $P < 0.01$ compared to PGE.

† $P < 0.001$ compared to PGE.

were measured by freezing point depression (Advanced Osmometer) and Na⁺ and K⁺ concentrations were measured by atomic absorption spectrophotometry (Pye Unicam). Prostaglandins were measured by specific radioimmunoassays^{2,11}. Statistical differences were calculated using the Student *t* test and correlations were assessed by the method of least squares.

The mean concentrations and excretions of PGE, PGF and PGFM in urine sampled daily from foetuses between 120-144 d of gestation are shown in Table 1. The concentration of PGE was significantly higher than the concentration of PGF ($P < 0.001$) or PGFM ($P < 0.01$). There was no correlation between the concentrations of PGE and PGF but the concentrations of PGF and PGFM were significantly related ($r = -0.67$, $P < 0.001$, $n = 23$). The concentrations of PGE, PGF and PGFM in urine were significantly greater than those previously described in foetal plasma and tracheal fluid (Table 2).

The concentrations and excretions of prostaglandins were not related to the arterial blood gases, haematocrit, or the pH of either blood or urine. The excretion of PGE, but not PGF or PGFM, increased with gestational age ($r = -0.62$, $P < 0.01$, $n = 18$). The ratio of the mean concentrations of PGE and PGF was 2.34 (see Table 1), although the most commonly observed (modal) value was 1.25. The excretions of PGE, PGF and PGFM were significantly related to the rate of urine flow (Table 3). The excretions of PGF and PGFM correlated with osmolar and solute-free water clearances and also with Na⁺ excretion, whereas the excretion of PGE was related only to the clearance of solute-free water.

The relatively high concentrations of prostaglandins in foetal urine strongly suggest that the foetal kidney is an important source of prostaglandins in the foetus and probably a major source of the prostaglandins found in amniotic fluid. The excretion of PGE is similar to its concentration in amniotic fluid implying a high turnover in the amniotic fluid. Excretion of prostaglandins in urine closely reflects biosynthesis by the kidney¹⁸. Prostaglandins enter urine from the medulla at the ascending limb of the loop of Henlé¹⁹ and, in the adult animal, undergo considerable intrarenal metabolism^{19,20}. Even assuming that minimal degradation of prostaglandins occurs within the

† $P < 0.01$ compared to prostaglandins in urine.

Table 3 Correlation of prostaglandin excretions (ng min⁻¹) with urine flow, osmolality, osmolar clearance, solute-free water clearance and sodium excretion

	U (ml min ⁻¹)	U _{osm} (mOsm/kg H ₂ O)	C _{osm} (ml min ⁻¹)	C _{H₂O} (ml min ⁻¹)	Na excretion (μEq min ⁻¹)
PGE excretion (n = 18)	+0.46*	NS	NS	+0.58*	NS
PGF excretion (n = 21)	+0.53*	NS	+0.45*	+0.65†	+0.49*
PGFM excretion (n = 21)	+0.86†	NS	+0.74†	+0.80†	+0.44*

Values are Pearson correlation coefficients: U, urine flow; U_{osm}, urine osmolality; C_{osm}, osmolar clearance; C_{H₂O}, solute-free water clearance; NS, not significant.

*P < 0.05.

†P < 0.001.

‡P < 0.01.

foetal kidney the excretion rates in the present study are high compared with the conscious adult rabbit²¹ and anaesthetised dog¹⁸. The foetal lamb kidney can metabolise prostaglandins¹², however, and relatively high levels of PGFM were found in foetal urine. Hence it is possible that the foetal kidney has a greater capacity for prostaglandin biosynthesis than that represented by the direct excretions of PGE and PGF.

The high concentrations of prostaglandins found in urine have important implications for several aspects of renal function in foetal life. Renal prostaglandins are known to modulate renin release, salt and water homeostasis and to potentiate adrenergic nerve activity (for recent reviews see refs 22, 23). It is possible that renal production of PGE may be partly responsible for the hypotonicity of foetal urine and poor concentrating ability of the kidney since PGE is known to antagonise the actions of vasopressin on the collecting duct²⁴ and to increase independently solute-free water formation by an action on the proximal tubule²⁵. This hypothesis is supported by the positive correlation found in the present study between the excretion of PGE and solute-free water clearance in foetal urine. Since prostaglandins may modulate the secretion of renin from the kidney²⁶ they may be responsible for the relatively high renin activity of foetal plasma²⁷. The correlation between the excretion of PGF and osmolar and Na⁺ excretion is consistent with the renin inhibiting actions of PGF_{2a} (ref. 28).

We thank Professors G. S. Dawes and A. C. Turnbull for their encouragement and the use of departmental facilities. This work was supported in part by the MRC. D.W.W. was a Nuffield Dominions Demonstrator. Prostaglandins and antisera to PGF and PGFM were the gifts of Dr K. T. Kirton (Upjohn); antiserum to PGE was a gift of Dr M. Withnall (May and Baker). We are grateful to Dr J. S. Robinson for his comments on this manuscript.

Physical and physiological properties of dry lung surfactant

The phospholipids of pulmonary surfactant¹ cover the respiratory epithelium and because of their unique properties of lowering surface tension, spreading rapidly and sustaining high surface pressures, allow the lungs to expand easily and prevent their collapse. Deficiency of lung surfactant is the major cause of respiratory distress syndrome in premature babies and also contributes to the respiratory problems of paraquat poisoning and cardiac bypass surgery. It has generally been assumed that surfactant, whether in the lamellar bodies or alveoli, is in an aqueous environment and must, therefore, be hydrated. We show here, however, that fully hydrated surfactant is apparently inactive and that surfactant can only be effective as a surface monolayer if the source of the material is 'dry'.

The critical micelle concentration (CMC) of the principal lung surfactant phospholipid, L-α-dipalmitoyl phosphatidylcholine, in water has the extremely low value of $4.6 \pm 0.5 \times 10^{-10}$ M (ref. 2). In consequence the overwhelmingly preferred domain for a single phospholipid molecule in water is in association with other phospholipid molecules. The resulting aggregates, technically referred to as smectic mesophases or liposomes, come to occupy a minimum space in the hostile environment of water. The reason for the low CMC of the molecule is the large and incompatible-in-water hydrocarbon moiety.

A liposome infrastructure³ is characterised by alternating bimolecular sheets of lipid intercalated by aqueous spaces, whereby each and every lipid sheet forms a 'closed' membrane system and where all the hydrocarbon chains are screened from water by the polar head-group region (Fig. 1a). It seems unlikely that this material, in a fully hydrated state, could facilitate a rapid extension of an air/fluid interface by donating surface-active molecules, for example, as occurs during the first inspiratory breath of an infant. Nevertheless there has been a tacit assumption that the lamellar bodies of alveolar type 2 cells are packages of lung surfactant, smectic mesophase in character, in equilibrium with cell water.

We suggest that the lamellar bodies are packages of phospholipids in equilibrium with restricted amounts of water—less than about 15 water molecules per phospholipid, at which proportion the bimolecular sheets of phospholipid are not closed but 'open' and the structure has more of the properties of a water-in-oil system than an oil-in-water system. On release from a cell close to an advancing air/fluid interface the phospholipids would rapidly and easily donate molecules to the interface, since these molecules do not have to surmount the unfavourable hydration barrier (Fig. 1b).

The surfactant used in our experiments was prepared by washing out sheep's lungs with saline, removing the cellular debris by centrifugation, concentrating the fluid by lyophilisation and extracting the complete lipid content by the Folch procedure⁴. The chloroform layer was evaporated to dryness under nitrogen leaving a dry, waxy material, the surfactant. This has been analysed and found to contain all the generally accepted surfactant lipids in normal proportions (J. Harwood, personal communication). In the experiments using wetted surfactant, liposomes were formed by sonicating the dry surfactant in saline. Surface tension measurements were made using a roughened platinum dipping plate (2 cm wide) suspended from a force transducer feeding into a recorder. The liquid was contained in a clean, Teflon trough.

When a particle of dry surfactant was placed on the clean surface of physiological saline the surface tension always fell rapidly to the equilibrium tension of $\sim 24 \text{ dyn cm}^{-1}$ (Fig. 2a). If a similar amount of wet surfactant was added to the surface there was either no effect on surface tension or else it fell very slowly to some variable, intermediate value (Fig. 2b).

In other experiments we rapidly removed as much of a surface monolayer as possible by aspiration with a fine tipped sucker (Fig. 2 at each arrow). When the surface layer had been formed from a particle of dry surfactant the surface tension rose with aspiration and then quickly fell again, within 20 s, showing that more molecules were being donated to the surface. This could be repeated many times, but only as long as there was a particle of surfactant at the surface to act as a molecular reservoir (Fig. 2a). Once the particle was removed further recruitment of molecules to the surface became very slow. When wet surfactant was used and the surface monolayer was aspirated, the surface tension rose and fell again very slowly because few molecules were being recruited to the surface (Fig. 2b).

The effect of dry surfactant on lung expansion was investigated by placing a small particle into the fluid-filled trachea of dead 27-d foetal rabbits (term is 31 d, and the lungs contain little endogenous surfactant at this age). Twenty-one foetuses from six litters were used; 22 alternate foetuses were used as untreated controls. A tracheostomy tube was connected to a closed circuit apparatus constructed to inflate and deflate the lungs and to plot pressure volume curves. Three cycles were performed on each lung at 37°C . Twenty-nine foetuses were subjected to pressures up to $35 \text{ cm H}_2\text{O}$ and 14 foetuses to pressures up to $30 \text{ cm H}_2\text{O}$. There was no difference in body weights and wet lung weights between the treated and control

Fig. 2 The surface tension lowering properties of *a*, dry surfactant and *b*, wet surfactant placed on saline. In both instances surfactant was placed on the surface at 'On'. The dry particle was removed from the surface at 'Off'. Upwards-pointing arrows indicate when the surface monolayer was partly removed by aspiration.

foetuses. All the 21 treated lungs expanded at opening pressures below $30 \text{ cm H}_2\text{O}$. Only 6 of the 22 untreated lungs expanded, all with opening pressures above $30 \text{ cm H}_2\text{O}$. The mean volume retained at atmospheric pressure was $0.41 \pm 0.75 \text{ ml}$ (s.e.m.) for the treated lungs and $0.038 \pm 0.012 \text{ ml}$ for the untreated. These differences are statistically significant.

An intact surfactant monolayer is vital to the healthy functioning of the lungs. It allows the lungs to expand with a minimal expenditure of energy and prevents atelectasis in expiration. To be effective a surfactant must maintain the monolayer from the moment of birth. If the surfactant in the lungs is fully hydrated it will not form a surface active layer easily or quickly and will not spread fast enough to maintain an intact surface film. From these experiments we have shown that the active form of surfactant is the 'dry' state. We postulate that the lamellar bodies in the alveolar type 2 cells, which are known to be surfactant stored ready for release into the alveoli, are packages of surfactant in a 'dry' state.

There have been many attempts to treat respiratory distress syndrome in the newborn with surfactant substances as a mist nebulised with water. Not surprisingly this has proved uniformly ineffective. Our results suggest that it may be possible to correct surfactant deficient states with 'dry' surfactant.

Vulnerability of methylcholanthrene-induced tumours to immunity aroused by syngeneic foetal cells

It is a well-observed fact that the growth of malignant tumours in experimental animals and in man is often accompanied by the renewed formation of embryonic or foetal substances the synthesis of which would normally have been switched off much earlier in life. This manifestation of anaplasia has often been reviewed¹⁻³. Among such foetal substances are antigens capable of arousing a cell-mediated immunity (CMI) directed both against embryonic cells and also against tumours. This makes it possible to perform experiments which would normally have been prohibited by the fact that the tumours induced by chemical oncogens are almost always antigenically *sui generis*. We present evidence that protection against tumours is secured by immunity to embryo-specific antigens aroused by normal pregnancy or by deliberate inoculation of embryonic cells. This might explain the known association between childbearing and the diminished risk of breast cancer.

A team at this institute had already shown² that the inoculation into CBA mice of irradiated cells isolated from 9-11-d-old CBA embryos 14 d before the subcutaneous injection of 50 µg of 3-methylcholanthrene (MCA) retards the onset and diminishes the final total frequency of tumours. They showed at the same time that when the inoculation of foetal cells was postponed until shortly before the first tumours were expected to arise (about 90 d), the MCA-induced tumours arose more quickly and in more mice. Further investigation (Fig. 1) confirmed the protective power of a foetal inoculum given 14 d before the administration of MCA, and showed again that an inoculum delayed until 14 d after MCA promoted the growth of tumours. The injection of a miscellany of irradiated adult CBA cells 14 d before MCA (under the conditions in which foetal cells are inhibitory) was without effect. In this experiment, however, the injection of adult cells 14 d after MCA caused some tumour promotion. This phenomenon, and the necessity for irradiation of the foetal inoculum if foetal cells are to be immunogenic, are still unexplained.

The balance between tumour promotion and tumour inhibition was now investigated in an experiment in which the ostensibly protective inoculum of foetal cells was administered 7 or 14 d before, or 7 or 14 d after the injection of 50 µg MCA.

The experiment was so arranged that the operation least easy to make uniform was carried out with a single homogeneous

Fig. 1 Cumulative curves of tumour incidence in male CBA mice which, in addition to receiving 50 µg 3-methylcholanthrene (MCA), received inoculation of 1×10^6 foetal or adult cells at various intervals before (—) or after (+): A, foetal cells 14 d after MCA (+14); B, adult cells (+14); C, MCA alone; D, adult cells (—14); E, foetal cells 14 d before MCA (—14). Note protective power of foetal tissues given before (E) but not after (A) MCA. Note also that curves C and D are virtually indistinguishable, showing that adult cells are ineffective under the conditions in which foetal cells confer protection. Adult cells injected 14 d after MCA (B) secure some degree of promotion.

batch of irradiated CBA foetal cells on a single occasion: each of 125 female CBA mice of the same provenance received 1×10^6 irradiated (2,000R) foetal cells belonging to a single batch isolated on the same occasion from 10-11-d-old CBA embryos. The injections of MCA (0.1 ml per mouse 5% MCA in olive oil) were so arranged that each of five groups of 25 mice received their injections of MCA 7 or 14 d before or after, or at the same time as, the injection of foetal cells, at the times indicated in Fig. 2. For logistic reasons, mice receiving MCA alone could not be included, but internal comparisons between the groups show very clearly that inoculation of embryonic cells 7 or 14 d after or at the same time as the injection of MCA was much less effective than the inoculation of foetal cells 7 or 14 d before MCA.

Fig. 2 Cumulative curves of tumour incidence in female CBA mice which, in addition to receiving 50 µg MCA, received inocula of 1×10^6 foetal cells either on the same occasion (0) or at 7 or 14 d before (—) or after (+): A, foetal cells +14; B, foetal cell injection +7; C, foetal cells and MCA simultaneous; D, cell injection —7; E, foetal cells —14. Note relative effectiveness of foetal tissue given before MCA (E, D), compared with the effect of a cellular inoculation at the same time as (C), or after MCA (A, B).

The failure of experiments of therapeutic rather than prophylactic design, and the fine balance between discouragement and promotion of the growth of tumours may perhaps explain the disappointing clinical results of specific tumour therapy. They may also help to account for some unexpected characteristics revealed in the large-scale multi-centre epidemiological studies of the Harvard School of Public Health^{4,5} on the influence of parity on susceptibility to mammary cancer in human beings: the risk of breast cancer decreases with increasing parity, but the principal determining factor is the age of the mother at the birth of her first child; the relatively protective effect of a completed pregnancy before the age of 20 may last for 50 years. The explanation of this phenomenon may be endocrinological, but there is strong evidence that it is immunological: Brawn⁶, Hellstrom⁷ and Simpson and Gautam (personal communication) have shown that pregnancy in mice excites the formation of lymphocytotoxic cells directed against foetus-specific and tumour antigens; Moon⁸, moreover, has shown that rats which have borne litters show an enhanced resistance to the mammary tumours induced by the oral administration of dimethylbenzanthracene. The Harvard collaborative study made it clear that women who bore their first children at the age of 33 or later were more susceptible than childless women to mammary tumours. So far from being inconsistent with an immunological interpretation, this finding is what might have been anticipated from our own experimental results. The effect of an early pregnancy is in a sense simulated by the results of experiments in which immunity is aroused before the application of the oncogenic stimulus; the lessened effectiveness, even increased hazard associated with late pregnancy is simulated by the enhancing effect on tumour growth consistently found when the ostensibly protective inoculation is deferred until after the application of the oncogenic stimulus. The underlying assumption in both situations is that the transformation from normal

to malignant growth occurs very shortly after inoculation of MCA and very early in reproductive life.

H-2 Antigens on a murine lymphoma are associated with additional proteins

THERE have been reports indicating that the normal phenotypic expression of histocompatibility antigens is altered on tumour cells¹, and a disappearance or diminution of H-2 expression on murine tumour cells has been demonstrated^{2,3}. The nature of these changes has so far remained unclear. It has also been shown that H-2D and H-2K antigens are important in T-cell mediated lysis of virus infected or transformed syngeneic cells^{4,5}. One explanation for these phenomena proposes that H-2 antigens are modified by association with additional cell-surface molecules to form a neoantigen or 'altered self'⁶. We report here immunochemical evidence for alteration of H-2 antigens on tumour cells by association with additional proteins.

An oestrogen-induced lymphoma (6C3HED) (obtained from Dr M. Prager, Dallas, Texas) was maintained in syngeneic C3H mice by weekly intraperitoneal transfer of approximately 10^6 tumour cells. We have observed that H-2.23, the private K locus antigen of the H-2^k haplotype, is undetectable on intact 6C3HED lymphoma cells by either cytotoxicity or absorption assays. This is in agreement with the results of Garrido *et al.*⁷. We have also observed, however, that a cell lysate produced by repeatedly freezing and thawing 6C3HED cells completely and specifically blocked the cytotoxic action of anti-H-2.23 on syngeneic normal cells. These data suggest that H-2.23 may be present on 6C3HED cells, but modified in such a way as to be undetectable on the intact tumour cell.

Normal C3H splenocytes and tumour cells were radiolabelled, extracted with 0.5% NP-40, and reacted with either anti-H-2.23 or normal mouse serum. The resulting antigen-antibody complexes were precipitated with Protein A-bearing *Staphylococcus aureus* and analysed by polyacrylamide gel electrophoresis in the presence of sodium dodecyl sulphate (SDS-PAGE).

There was a marked difference in the reactivity of anti-H-2.23 with normal C3H cells and with 6C3HED tumour cells (Fig. 1). Proteins with mobilities corresponding to molecular weights of 45,000 and 12,000 characteristic of detergent-solubilised H-2 and β_2 -microglobulins (β_2 - μ), respectively, were present in both electropherograms. Additional major peaks with mobilities indicative of molecular weights of approximately 70,000 and 55,000 were evident in the 6C3HED cell extract. To establish further that the protein peaks at 45,000 and 12,000 were H-2 and β_2 - μ and to determine whether H-2 antigens on the tumour cells are associated with β_2 - μ , additional experiments were carried out using a rabbit anti-rat β_2 - μ . This antiserum cross reacts with mouse β_2 - μ (ref. 8) and was prepared against homogeneous rat urinary β_2 - μ , which had been shown to give a unique amino acid sequence (M. Poulik, D. Schinnick and O. Smithies, unpublished); the specificity of this antiserum is known⁸. SDS-PAGE analyses of antigens isolated from biosynthetically labelled C3H splenocytes or 6C3HED tumour cells with rabbit anti-rat β_2 - μ are shown in Fig. 2. When tested with normal splenocytes, the anti- β_2 - μ produced peaks characteristic of β_2 - μ and detergent-solubilised H-2. When reacted with tumour cells, this antiserum also

Fig. 1 SDS-polyacrylamide gel electrophoresis of murine lymphoid cell antigens isolated with anti-H-2.23 antiserum (K603). Cells were teased from whole C3H spleens or obtained from the ascites fluid of tumour-bearing mice, washed, counted, and adjusted to a concentration of 5×10^7 viable cells per ml in RPMI 1640 containing $100 \mu\text{Ci ml}^{-1}$ ^3H -leucine and incubated for 5 h at 37°C in a 5% CO_2 -95% air mixture. The cells were then collected, washed, and extracted in 0.5% NP-40 (v/v) in Tris-buffered saline (0.05 M, pH 8.0) for 30 min at 4°C . The extract was centrifuged at $45,000g$ for 15 min and the pellet discarded. Aliquots (100 μl) of the supernatant were incubated with 20 μl of antiserum for 1 h at 37°C , then overnight at 4°C . Indirect immunoprecipitation with 250 μl of 10% v/v heat-killed formalin-fixed *Staphylococcus aureus* (Staph A) (Cowan 1 Strain) and SDS-PAGE on 12.5% gels was carried out as described by Kessler¹⁶. a, N.C3H splenocytes; b, 6C3HED lymphoma cells. ●, Anti-H-2.23; ○, normal mouse serum. Molecular weight standards were bovine serum albumin, ovalbumin, carbonic anhydrase and cytochrome c.

produced the higher molecular weight peaks which were obtained with anti-H-2.23 as well as the H-2 and β_2 - μ peaks. Similar peaks were obtained when anti-H-2.23 and anti- β_2 - μ were reacted with NP-40 eluates of tumour cells which had been radioiodinated with lactoperoxidase. This indicates that the antigens detected were present on the cell surface.

To eliminate the possibility that antibodies reactive with antigens other than β_2 - μ were responsible for the precipitation of additional proteins, the rabbit anti-rat β_2 - μ was prereacted with highly purified rat β_2 - μ or bovine serum albumin (BSA) and then added to a radiolabelled extract of 6C3HED cells. The result of SDS-PAGE analysis of the precipitate is shown in Fig. 2b. The fact that preincubation of the antiserum with purified β_2 - μ reduced all peaks to background level, whereas prereaction with BSA had no effect, strongly suggests that the reactivity of this antiserum with the 6C3HED can be attributed to anti- β_2 - μ antibodies.

Although the reactivities of both anti-H-2 and anti- β_2 - μ antisera with normal and tumour cell extracts were very similar, it was not obvious whether or not they were reactive with the same antigenic structures. Immunoabsorbents (IADS) were therefore prepared by covalent attachment of crude Ig fraction of NRS or rabbit anti-rat β_2 - μ to CNBr-activated Sepharose 4B (ref. 9) and were incubated overnight with radiolabelled extracts of 6C3HED tumour cells. The IADS was then removed by centrifugation and the supernatants immunoprecipitated with anti-H-2.23 or rabbit anti-rat β_2 - μ . SDS-PAGE analyses of these immunoprecipitates are shown in Fig. 3. Precipitation of the H-2, β_2 - μ , and the higher molecular weight peaks by anti-H-2.23 or anti- β_2 - μ was unaffected by previous reaction of the tumour cell extract with the NRS immunoabsorbent. Previous reaction of the tumour cell

extract with the anti- $\beta_2\text{-}\mu$ IADS, however, resulted in removal of all proteins reactive with either anti-H-2.23 or anti- $\beta_2\text{-}\mu$.

There are several possible explanations for the coprecipitation of H-2, $\beta_2\text{-}\mu$, and the higher molecular weight proteins from tumour cell extracts following reaction of both anti- $\beta_2\text{-}\mu$ and anti-H-2 with the lymphoma cells. First, both K603 (anti-H-2.23) and the anti- $\beta_2\text{-}\mu$ sera could be contaminated with additional antibody. We have not established definitely that this is not the case with the anti-H-2.23 antisera, however, since the rabbit anti-rat $\beta_2\text{-}\mu$ was prepared in rabbits against highly purified rat urinary $\beta_2\text{-}\mu$, it seems unlikely that this antiserum was contaminated with additional antibodies reactive with material present only on mouse tumour cells. Second, the apparent association might be an artefact of the extraction procedure, but the proteins are probably not part of a large lipid-detergent micelle since H-2K, H-2D and Ia antigens present in similar extracts of normal C3H splenocytes are easily separated. Complex formation due to disulphide interchange during extraction is also unlikely since identical electropherograms were obtained when the extraction was carried out in the presence of 10 mM iodoacetamide. The appearance of additional proteins in the immunoprecipitate from the tumour cell extracts is not caused by nonspecific binding of proteins to the antigen-antibody complex, since the addition of unlabelled $\beta_2\text{-}\mu$ to the reaction mixture prevented the precipitation of any radiolabelled material. Clearly, then, $\beta_2\text{-}\mu$ protein complexes not present in extracts of normal cells are found in extracts of the 6C3HED tumour cells.

Two explanations exist to account for the relationship between the reactivities of the rabbit anti-rat $\beta_2\text{-}\mu$ and the anti-H-2.23. First, the anti-H-2 antiserum could contain additional antibodies which are reactive with material present on tumour cells but absent from normal cells. These additional antigens, as well as H-2, must be associated with $\beta_2\text{-}\mu$ since prereaction of the 6C3HED cell extracts with the anti- $\beta_2\text{-}\mu$ adsorbent removed all material reactive with anti-H-2. To date, $\beta_2\text{-}\mu$ has been shown to be associated only with H-2 (ref. 10), TLA (ref. 11), and Qa-2 (ref. 12) on the surface of normal cells. A second possibility is that a complex composed of at least one $\beta_2\text{-}\mu$, one H-2 heavy chain and one or two higher molecular weight proteins is formed on the tumour cell. In detergent extracts, this complex precipitates with anti-H-2.23 and anti- $\beta_2\text{-}\mu$ as a single entity. The complex is reduced to its individual protein components when the precipitates are prepared for SDS-PAGE.

At present, we cannot distinguish unequivocally between these two possibilities, but we consider the latter to be the more plausible explanation since four different anti-H-2.23 antisera,

Fig. 2 SDS-PAGE of lymphoid cell antigens isolated with rabbit anti-rat $\beta_2\text{-}\mu$. 100 μl of an extract of either *a*, N.C3H splenocytes or *b*, 6C3HED lymphoma cells was reacted with 20 μl of rabbit anti-rat $\beta_2\text{-}\mu$ antiserum which had been prereacted with either 200 μg of BSA (●) or 100 μg of purified $\beta_2\text{-}\mu$ (○).

Fig. 3 SDS-PAGE of murine lymphoid cell antigens: effect of pretreatment with immunoadsorbent. Extracts of 6C3HED lymphoma cells were incubated overnight with an immunoadsorbent (100 μl adsorbent per 100 μl extract) prepared by coupling the crude Ig fraction of either rabbit anti-rat $\beta_2\text{-}\mu$ (○) or normal rabbit serum (●) to CNBr-activated Sepharose 4B to a final concentration of ~ 10 mg protein per ml beads. The adsorbent was removed and the supernatant incubated with either *a*, anti-H-2.23 (K603) or *b*, rabbit anti-rat $\beta_2\text{-}\mu$.

including (C3H.OH \times B10.129) against C3H [K603], (B10 \times LP.RIII) against B10.A(2R) [K358], (B10.RIII (7INS) \times DBA/2) against B10.A [K323] and (B10.D2 \times A) against B10A (5R) [D23], gave identical patterns of reactivity in SDS-PAGE analysis of immunoprecipitates of radiolabelled 6C3HED cell extracts. It seems unlikely that all of these antisera would contain precisely the same contaminating antibodies. In addition, preliminary results indicate that anti-H-2 antisera which have been absorbed with normal C3H splenocytes are completely unreactive with extracts of 6C3HED cells. This suggests that the anti-H-2 antisera do not contain additional antibodies which are reactive with materials present only on the tumour cells.

Henning *et al.*¹³ have shown that viral antigens are present in close association with H-2 antigens on the surface of EL-4 leukaemia cells. Furthermore, Fujimoto *et al.*¹⁴ have shown that H-2 is associated with a tumour-associated antigen in the sera of lymphomatous A/J mice and Gooding and Edidin¹⁵ have shown that H-2 is physically linked to an additional antigenic moiety on the surface of teratoma cells. We have presented evidence which strongly suggests that the H-2- $\beta_2\text{-}\mu$ dimer is associated with additional proteins on the surface of 6C3HED lymphoma cells. Furthermore, syngeneic anti-tumour antisera, which are unreactive with normal C3H cells, precipitate the same material from tumour cell extracts that is reactive with anti-H-2.23 (to be published elsewhere). These data suggest that a new complex is formed on the surface of these tumour cells and that this complex contains not only H-2 and $\beta_2\text{-}\mu$ antigenic determinants but also tumour-associated antigens.

We thank Dr Jan Klein for the antisera K603, K358, and K323; rabbit anti-rat $\beta_2\text{-}\mu$ was provided by Dr M. D. Poulik; antiserum D23 was obtained from the Transplantation Immunology Branch of NIAID, Bethesda, Maryland. This work was supported by the USPHS.

Anti-idiotypic antibodies against anti-vitamin A transporting protein react with prealbumin

IDIOTYPIC determinants on antibodies are those antigenic determinants in one antibody population which are not present in another antibody population from the same animal¹. The restriction of a set of idiotype determinants to antibodies directed against a single antigen suggests that the idiotype determinants may reside in the antibody combining site. In fact, amino acid sequence determinations of antibodies sharing the same idiotype have shown that the variable portions of light chains as well as heavy chains of the various antibodies are very similar if not identical (see ref. 2 for review). These and similar observations have suggested that antibodies against the idiotype determinants (anti-idiotypic antibodies) recognise only a clonotype, that is, antibodies with a given set of variable regions. This seems well founded in as much as antibodies raised in two species against a single antigen only infrequently seem to share idiotype determinants. Since the antibody system is degenerate then some antibodies raised against a protein antigen, called A, which forms part of the protein-protein complex AB, may recognise protein A in a fashion similar to that of the normally interacting protein B. Consequently, the idiotype determinants of some of the antibodies against protein A may have structures in common with protein B. If so, antibodies raised against such idiotype determinants should bind to protein B. To test this assumption we explored the situation with regard to the retinol-binding protein (RBP)-prealbumin protein complex³⁻⁶. The data presented here show that it is possible to raise anti-idiotypic antibodies against anti-RBP and that such antibodies interact with prealbumin.

Human RBP and prealbumin were isolated as described previously³. Various chemical, physical-chemical, and radio-immunological tests revealed that both proteins were free from cross-contamination (for details see ref. 7). Rats were immunised with RBP⁸ and after several booster injections the rats were exsanguinated and the serum collected. Sera from 10 rats were pooled to obtain sufficient amounts for further processing. Antibodies against human RBP were isolated by immunosorbent purification on a Sepharose 4B column to which RBP had been covalently attached⁹. The bound antibodies were desorbed with 0.2 M glycine-HCl buffer pH 2.9. Although RBP which has been subjected to acid does not interact with prealbumin⁹ it was important to ascertain that the RBP antibody preparation did not contain any rat prealbumin. To this end the antibody preparation was labelled¹⁰ with ¹²⁵I and immunoprecipitated with a specific anti-rat prealbumin serum by a sandwich procedure¹¹.

Although this test did not reveal the presence of any prealbumin it is likely that if prealbumin represented less than about 0.002% of the total protein its presence would have escaped detection. Furthermore, heavily overloaded SDS-polyacrylamide gels¹¹ did not reveal any protein zones which could be identified as prealbumin after electrophoresis; more than 98% of the antibody preparation labelled

Fig. 1 Binding of anti-idiotypic antibodies against anti-RBP to ¹²⁵I-labelled prealbumin. The anti-idiotypic antibody preparation (initial concentration 2 mg ml⁻¹) was serially diluted and mixed with ¹²⁵I-labelled prealbumin (32,000 c.p.m.). The resulting immune complexes were collected by the use of protein A-containing *Staphylococcus aureus*¹¹. As a control serial dilutions of preimmune rabbit IgG of the same concentration as the anti-idiotypic antibodies was used. ●, Anti-idiotypic antibodies; ■, preimmune IgG.

with ¹²⁵I was precipitated by a rabbit anti-rat IgG serum; and immunoelectrophoresis of the anti-RBP preparation revealed a single precipitin line with a polyvalent rabbit anti-rat serum protein serum. All of these criteria, and others which we shall describe, suggested that the isolated rat anti-RBP antibodies were of high purity.

The specific rat antibodies against RBP were injected into a rabbit which was repeatedly challenged with the antibodies over a period of 3 months. Theoretically, the rabbit antiserum contained antibodies against the common portions of rat immunoglobulin as well as antibodies to the particular idiotype determinants. The IgG of the rabbit serum was isolated on a goat anti-rabbit IgG-Sepharose 4B immunosorbent column. To remove antibodies against the common rat IgG determinants the rabbit IgG fraction was passed over an immunosorbent column of Sepharose 4B containing covalently bound normal rat IgG. Material which passed the column unretarded did not bind to ¹²⁵I-labelled normal rat IgG but reacted with ¹²⁵I-labelled rat antibodies against RBP. Thus, the rabbit antibodies, isolated as described, were apparently specific for idiotype determinants present on rat antibodies against RBP.

To test whether the anti-idiotypic antibodies against anti-RBP would react with human prealbumin, the latter protein was labelled with ¹²⁵I and mixed with serial dilutions of the anti-idiotypic antibodies. The resulting immune complexes were collected as described¹¹. In a control experiment the anti-idiotypic antibodies were replaced by preimmune rabbit IgG. Figure 1 shows that the anti-idiotypic antibodies reacted with prealbumin. In all tests performed the anti-idiotypic antibodies could bind more than 90% of the labelled prealbumin. Preimmune rabbit IgG did not react with prealbumin (Fig. 1), suggesting that the reaction was specific.

The titre of the anti-idiotypic antibodies was low; 1 ml of antiserum could bind 160 ng of human prealbumin and 120 ng of rat prealbumin. One ml of a regular rabbit anti-serum against rat prealbumin bound 150 µg of rat prealbumin but only 10 ng of human prealbumin. These observations show that the immunological cross-reactivity between human and rat prealbumin, as for RBP¹², is low and, thus, the data are consistent with the view that the rabbit anti-anti-RBP serum did not contain any antibodies that had been raised against prealbumin directly.

If the antibodies reactive with prealbumin are genuine

anti-idiotypic antibodies against anti-RBP the binding between prealbumin and these antibodies would be abolished in the presence of antibodies against RBP. To examine this ^{125}I -labelled human prealbumin and anti-idiotypic antibodies against anti-RBP were mixed together with serial dilutions of two rat IgG fractions. One fraction contained rat antibodies against RBP whereas the other fraction comprised only preimmune IgG from the same rats. Figure 2 shows that preimmune rat IgG did not affect the reaction between ^{125}I -labelled prealbumin and the anti-idiotypic antibodies. This reaction was completely inhibited in the presence of rat antibodies against RBP, however.

The same experiment was repeated with a regular rabbit antiserum against rat prealbumin substituting for the anti-idiotypic antiserum. In this case neither rat anti-RBP nor preimmune rat IgG had any effect on the binding of the prealbumin-antibodies to prealbumin (not shown). These data give strong support to the view that it was the anti-idiotypic antibodies against RBP which recognised prealbumin.

Since there is no apparent immunological cross-reactivity between RBP and prealbumin⁸ it seemed likely that the anti-idiotypic antibodies against RBP recognised the RBP-binding site on the prealbumin molecule. If so, RBP should abolish the interaction between the anti-idiotypic antibodies and prealbumin. To examine this various amounts of RBP were added to a mixture of ^{125}I -labelled prealbumin and the anti-idiotypic antibodies. As a control RBP was replaced by soy bean trypsin inhibitor. Figure 3 shows that RBP, but not soy bean trypsin inhibitor, completely abolished the interaction between prealbumin and the anti-idiotypic antibodies. This suggests that the anti-idiotypic antibodies bound to the RBP-binding site on prealbumin.

To explain why anti-idiotypic antibodies raised against anti-RBP interact with prealbumin it seems reasonable to assume that a portion of the antibodies raised against RBP recognises this protein in a way similar to the way prealbumin recognises RBP. Due to the degeneracy of the antibody system, some of the combining sites of the antibodies may in fact be very similar to those structures of

Fig. 2 Competition for binding to the anti-idiotypic antibodies against anti-RBP between prealbumin and rat antibodies against RBP. ^{125}I -labelled prealbumin (30,000 c.p.m.) was mixed with enough anti-idiotypic antibodies to cause 80% binding and serial dilutions of specific rat antibodies against RBP (initial concentration 0.5 mg ml^{-1}). As a control the rat antibodies were replaced by preimmune rat IgG at a concentration identical to that of the RBP antibodies. Immune complexes were precipitated as described before¹¹. ●, Rat antibodies against RBP; ■, pre-immune rat IgG.

Fig. 3 Competition for binding to prealbumin between RBP and anti-idiotypic antibodies against anti-RBP. ^{125}I -labelled prealbumin (29,000 c.p.m.) was mixed with enough anti-idiotypic antibodies to ascertain 80% binding and serial dilutions of highly purified RBP (initial concentration 0.25 mg ml^{-1}). As a control soy bean trypsin inhibitor was used instead of RBP. Immune complexes were collected as described¹¹. ●, RBP; ■, soy bean trypsin inhibitor.

prealbumin which binds to RBP. If so, a second set of antibodies raised against such antigen-combining sites would cross-react with prealbumin. The reaction with prealbumin should be confined only to that part of the molecule which binds to RBP. This is indeed the finding since RBP competes efficiently with the anti-idiotypic antibodies for binding to prealbumin despite the fact that antibodies raised directly against prealbumin will react with this protein regardless of whether RBP is bound or not⁸.

Only a subset of the anti-idiotypic antibodies would recognise prealbumin since RBP displays multiple antigenic sites⁸. In fact, RBP interacts with a cell-surface receptor with a site that is distinct from the prealbumin-binding site^{4,12}. Another subset of anti-idiotypic antibodies against anti-RBP abolishes the interaction between RBP and the cell surface receptor (K.S. and P.A.P., in preparation).

If generalised, the method described here to raise antibodies reactive with a protein which never was used in the immunisation procedure would be useful in obtaining antibodies against interacting proteins when only one of the proteins is available. Consequently anti-idiotypic antibodies against insulin would react with the insulin receptor. Preliminary observations in our laboratory suggest that this may indeed be the case.

Transient increase in muscarinic acetylcholine receptor and acetylcholine esterase in visual cortex on first exposure of dark-reared rats to light

AN organised sequence of cellular events, some transient, others more lasting, occurs in the visual system on first exposure of dark-reared rats to the light. Hitherto these changes have been biochemically characterised only in terms of rates of change of precursor uptake into protein fractions or *in vitro* assayed enzyme activities. We have shown that, in the visual cortex, the onset of visual experience is accompanied by a modulation of the total functional quantities of two classes of macromolecule with reasonably well understood functions in the cellular economy. One is the colchicine-binding microtubular protein, tubulin¹. We report here rapid transient changes in the amount of a protein known to be involved in synaptic functions, the muscarinic cholinergic receptor (mAChR), on the onset of light.

We showed previously that there is an elevation in the synthesis or turnover of several protein fractions in the visual cortex, as well as the lateral geniculate and retina^{2,3}. In the cortex, much of this increase is associated with a rapidly labelling and exported neuronal (glyco-)protein fraction⁴ whose transport is blocked by colchicine⁵. The microtubule system is apparently involved, since within 1 h of the onset of light, incorporation of ³H-lysine into a polymerisable tubulin fraction doubles⁶ and within 3 h there is a 23% elevation in the amount of colchicine-binding protein (largely tubulin) in the visual cortex¹. Over the same period, there is an increase in the activity of several acid hydrolases of up to 30%⁷.

All the changes listed above seem to be lasting, in that they persist for longer than 24 h and/or are present when dark-reared animals are compared to normally-reared littermates, with the exception of the elevation in colchicine-binding, which does not last beyond 24 h of light exposure. However, we have also found presumptive evidence for some apparently transient increases in the activity of the enzymes of acetylcholine metabolism, choline acetyltransferase (CAT) and acetylcholinesterase (AChE), in that while dark-reared animals did not differ in visual cortex enzyme activity from their normally-reared littermates, 3 h of light exposure of the dark-reared animals did produce a 30% elevation of activity of both enzymes⁷.

The transmitter(s) involved in the mammalian visual system are not known for certain, and the mere presence of relatively high concentrations of ACh and its enzymes is not, in itself, sufficient evidence for a transmitter role. However, the recent development of techniques for the detection and measurement of specific receptor binding proteins have shown the presence of significant quantities of a muscarinic cholinergic receptor at cortical synapses⁸. It has therefore become possible to examine the effects of dark rearing and visual experience on a molecule which may play a key part in the inter-neuronal transmission machinery.

Male Wistar rats were born and maintained in the dark until 50–55 d of age, at which time half of each litter was exposed, in individual cages, to normal laboratory illumination for 3 or 24 h (light exposed, L); the remainder were held in the dark, also in individual cages (dark controls, D). To avoid complications due to diurnal rhythmicity (N. Wood and S.P.R.R., in preparation) all exposures were carried out during the morning. In some experiments, a proportion of the littermates were removed from the dark at weaning (21 d) and subjected to a normal animal house

environment (12 h light, 12 h dark) until 50 d (normals, N). Experiments comparing L and D, D and N, and, in the AChE experiments, L, D and N groups, were made. Rearing conditions were exactly as described previously^{1,3}. Following treatments, L, D and N animals were killed, visual and motor cortex samples removed from each and homogenised in 0.05 M Na-K phosphate buffer, pH 7.4. Homogenates were either assayed directly or frozen until used. Preliminary experiments showed that freezing and thawing up to three times had no effect on the parameters to be measured.

Portions of each homogenate were assayed for: (1) muscarinic cholinergic receptor binding; (2) acetylcholinesterase; and (3) protein. Measurement of the muscarinic binding was based on the 3-quinuclidinylbenzilate (QNB) method of Yamamura and Snyder⁹ (see Table 1). Acetylcholinesterase (EC 3.1.1.7) was measured by the method of Ellman *et al.*¹⁰ and protein by that of Lowry *et al.*¹¹. Balanced groups were used in each experiment and batch variation in the mean QNB binding or AChE activity between experiments was eliminated by standardising results between batches. Statistical comparisons between groups were made using a two-tailed Student's *t*-test.

Figure 1 compares QNB binding in visual and motor cortex in 3- and 24-h light-exposed animals with that in their dark control littermates. At 3 h after the onset of light exposure, there was a 54% increase in QNB binding in the visual cortex of L compared with D animals ($t = 2.89$, $P < 0.01$). In the L animals, QNB binding in the visual cortex was 46% greater than in the motor cortex ($t = 2.33$, $P < 0.05$). There were no significant differences between binding in the visual and motor cortex of D animals, or between L and D animals in the motor cortex. However, the enhancement of QNB binding in the visual cortex of L animals was transient, as by 24 h binding activity had returned to the control level. A further indication that the effect was a transient response to the onset of light stimulation is given when QNB binding is compared in D and N animals (Table 1). There were no differences between animals in the two conditions, so light exposure cannot be necessary for the long-term normal development of cortical mAChR.

AChE activity was then measured in the same tissue samples. There were no differences in motor cortex levels

Fig. 1 ³H-QNB binding (black bars) was determined (open bars) in visual and motor cortices of dark-reared and light-exposed littermates aged 50–55 d as described in Table 1. Light exposure was for 3 h (a) or 24 h (b). Results are means of ≥ 16 animals in each case; error bars show s.e.m. Significance values are given in text. Results are expressed as standardised ³H-QNB radioactivity such that 1,000 d.p.m. \approx 1.0 pmol QNB bound per mg protein, but 3- and 24-h experiments are not directly comparable.

at either time, or between D and N animals in the visual cortex. There was a 24% elevation in visual cortex specific activity in L compared with D, and 18% in L compared with N, and both differences are significant (L versus D, $t = 3.94$, $P < 0.001$; L versus N, $t = 2.70$, $P < 0.02$). However, by 24 h the AChE activity in the L visual cortex had declined towards the controls and the difference is no longer significant ($t = 0.45$). The elevation of L over D at 3 h replicates our previous observation⁷ and the decline at 24 h confirms the prediction made in that paper.

These experiments, together with our earlier ones, demonstrate that the activities of the three components of the acetylcholine transmitter system in the visual cortex are responsive to the onset of visual input in dark-reared animals. CAT⁷, AChE and mAChR all show an elevation of specific activity of 24–54% within 3 h of the onset of light exposure; however, the response is transient, and by 24 h has disappeared.

These observations have two sets of implications. The first relates to understanding the mechanisms whereby experiential events (including learning) modulate neuronal connectivity. It is known that in the rodent, visual experience results in long-term changes in dendritic branching, spine formation and synaptic number and density^{12–14}. While enhanced protein synthesis and turnover of microtubular protein may underly these morphological changes^{2,4,6}, it seems that they do not involve a permanent increase in the activity of the ACh transmitter system per mg cortex protein. However, it is also well known that the fixation of experience in the brain is at least a two-stage process, the first being labile, the second more lasting, and that these stages can be uncoupled by the selective use of biochemical inhibitors (see, for example, ref. 15). Mobilisation of CAT–AChE–mAChR system could represent an aspect of synaptic potentiation associated with the labile phase of the fixation of experience. It is important to note that, unlike the enzyme activity measurements, those of mAChR involve a more direct assay of the number of

receptor molecules, or binding sites, present.

The second question raised by our observations relates to their molecular basis. Enhanced enzyme or binding activity could result from an activation or unmasking of pre-existing sites, or from a temporary increase in the *de novo* synthesis of the enzymes and receptors. To distinguish between these alternatives would provide evidence as to the nature of the control processes involved. Experiments to test this, and to clarify the subcellular locus of the enhanced QNB binding, are in progress.

We thank J. Mortimer for technical assistance, members of the Open University Brain Research Group for discussion and comments, T. Hedges for maintenance of the dark-reared rats and Dr G. B. Ansell of the University of Birmingham for advice on the assay procedure.

Table 1 ³H-QNB binding in visual and motor cortex of dark-reared and normal littermates

Condition	Standardised ³ H-QNB binding (d.p.m./mg prot.) in:— visual cortex	motor cortex
Normals	983 ± 78 (16)	1,011 ± 107 (16)
Dark-reared	871 ± 125 (13)	923 ± 60 (12)

Aliquots of homogenate containing between 50 and 120 µg protein were incubated in a reaction mixture containing 52 pmol. ³H-QNB, specific radioactivity 8–8.9 Ci mmol⁻¹ (Radiochemical Centre, Amersham) in the presence or absence of 125 nM atropine and 0.05 M Na-K-phosphate buffer, pH 7.4, to a final volume of 2.0 ml. Incubations were at 25 °C for 60 min and each sample was assayed six times, three times with, and three times without, atropine present. After incubation, the reaction mixture was filtered under suction through 2.5 cm Whatman GF/B filter disks and washed rapidly three times with 5 ml ice-cold Na-K phosphate buffer. The disks were dried for 1 h at 45 °C and counted in a toluene-phosphor scintillant containing 0.2% v/v Triton X-100. Specific QNB binding (p mol per mg protein) was calculated from the mean difference in bound counts in the absence and presence of atropine. Preliminary experiments confirmed the applicability of the assay to unfractionated tissue homogenates. Binding in the presence of atropine was generally some 50–60% of that in its absence and increasing the atropine concentration did not further reduce it. No artefactual atropine-sensitive binding to the filters in the absence of tissue occurred. The variability within triplicate assays of the atropine-sensitive binding was generally within the range ±15% and assays that fell outside these limits were discarded or repeated. The assay was linear with increasing tissue concentration, and average binding, of 0.8–1.2 pmol QNB per mg tissue protein, was similar to that reported by Yamamura and Snyder⁹. Binding was determined in visual and motor cortices of dark- and normally-reared littermates aged 50–55 d. Values are ± s.e.m. with the number of animals tested shown in parentheses. There are no significant differences between any group. Standardisation is such that 1,000 d.p.m. ≈ 1.0 pmol QNB per mg protein.

Rapid accumulation of high molecular weight acetylcholinesterase in transected sciatic nerve

NERVOUS tissue and muscle in rat^{1–4} and chicken^{5,6} contain several molecular forms of acetylcholinesterase (EC 3.1.17, AChE), distinguishable by their sedimentation coefficient in sucrose gradient⁷. In rat, several peripheral nerves and non-innervated regions of skeletal muscle^{1,2} were shown to contain two molecular forms of AChE, with respective sedimentation coefficients of 4 and 10S; in addition to these two forms, a high molecular weight form with a sedimentation coefficient of 16S was found in the innervated regions of various skeletal muscles^{1,2,4}. After denervation, the 16S form, which we will call the H form, either disappeared from skeletal muscle² or was drastically reduced^{1,4}. In chicken, several nerves exhibited three molecular forms of AChE with sedimentation coefficients of 4, 6.5 and 11S, while various skeletal muscles contained an additional molecular form with a sedimentation coefficient of 19.5S (ref. 5). After denervation, the high molecular weight form 19.5S, which by analogy with the 16S of rat is referred to here as the H form, disappeared from crude extract of muscles⁵. As the H form was only found in tissues innervated by cholinergic nerve endings and disappeared or decreased drastically from denervated skeletal muscles, it has been suggested that this form of AChE is exclusively myogenic^{1,3} and may constitute the specific endplate enzyme^{1,2,4,5}. We report here that tiny amounts of the H form of AChE can be detected in crude extracts of intact sciatic nerves of rat and chicken, and that after transection of the sciatic nerve with the ensuing blockade of the axonal traffic, the H form increased rapidly at the site of injury.

Fig. 1 AChE accumulation in transected sciatic nerve of rat (●) and chicken (○). Nerves were transected with scissors near the peroneal-tibial branching in rat and the ischiatic-femoral branching in chicken. At 6, 12, 18 and 24 h after transection, animals were killed and a 2-mm segment was cut off the tip of the proximal stump. The segment was homogenised in 1 M NaCl, 0.01 M Tris-HCl pH 7, 0.05 M MgCl₂ and 1% Triton X-100, and centrifuged at 20,000g for 20 min at 4 °C. The AChE was assayed in the supernatant at 20 °C, by the method of Ellman *et al.*¹² with acetylthiocholine as substrate and 10⁻⁴ M methopropazine as pseudocholinesterase inhibitor. One unit corresponds to hydrolysis of 73.5 nmol acetylthiocholine per min (ref. 13). Three animals per time-point were used.

Young Leghorn chicks (4 weeks old) and Wistar rats (2 months old) were anaesthetised with chloroform and one sciatic nerve was intersected by cutting out a 2-mm segment for use in measuring AChE concentrations in intact nerves (see legend to Fig. 1). At various intervals after transection (Fig. 1) the animals were killed and 2-mm segments cut off the end of the proximal stump. Nerve segments were then homogenised and the amount of AChE in the homogenate was determined (see legend to Fig. 1). Homogenates were then sedimented

through sucrose gradient to allow separation and characterisation of the different molecular forms of AChE (legend to Fig. 2).

In intact sciatic nerve of rat and chicken, AChE concentrations in the segment next to the site chosen for nerve transection were respectively 10 and 55 mU mm⁻¹ (for definition of unit see Fig. 1 legend). In both rat and chicken, separation procedure revealed the presence of four molecular forms of AChE (Fig. 2, 0 h). In rat sciatic nerve, we found a tiny amount (1.6%) of the H form (16.5S), one major form of 10S (M) which accounted for 63% of total AChE, and two low molecular weight forms (L) with respective sedimentation coefficients of 4S (L₁) and 6.5S (L₂), which accounted for 28 and 7.4% of total AChE. In chicken sciatic nerve, the H form (20S) only accounted for 1.3% of total AChE; the M form (73%) had a sedimentation coefficient of 11.5S; the two L forms had sedimentation coefficients of 5S (L₁) and 7S (L₂) respectively and accounted for 6 and 20% of total AChE. The presence of such small amounts of the H form in sciatic nerve of rat and chicken might explain why this form was not previously detected in nerve extracts^{1,2,5}. Detection of the H form, as well as of the 6.5S form in rat, which had also not been seen previously^{1,2}, was possible because of the higher resolution attained with the SW 41 Beckman rotor.

AChE activity in the 2-mm terminal segment from the proximal stump of the transected sciatic nerve, increased linearly during the 6th and 24th hours after transection (Fig. 1), at a rate of 4.2 mU h⁻¹ in rat and 47 mU h⁻¹ in chicken. To identify the molecular forms of AChE responsible for this rise in AChE activity, the crude extracts of the 2-mm segment were analysed by sedimentation in sucrose gradient. The sedimentation profile of AChE activity showed that only the activity of the two high molecular weight forms M and H increased with time, while that of the two low molecular weight forms L₁ and L₂ either remained unchanged or increased slightly (Fig. 2). The rise in the activity of the H form was very striking: 6 h after nerve transection, its concentration had increased 15-fold in rat and 20-fold in chicken (Fig. 3). For the M form, the rise was comparatively less pronounced, even though this form was responsible for most of the total increase in AChE activity,

Fig. 2 AChE sedimentation profiles in intact (0 h) and transected sciatic nerves of rat (a) and chicken (b). The 20,000g supernatant (see Fig. 1) was mixed with two markers: ADH (alcohol dehydrogenase, 4.8 S, Boehringer) and Z (β-galactosidase, 16S, Boehringer), layered on a 5–20% sucrose gradient and centrifuged in a SW 41 rotor (Beckman). Approximately 70 fractions were collected. Each fraction was assayed for AChE, ADH and Z.

Fig. 3 Accumulation kinetics for the high molecular weight forms of AChE. The rise in the activity of each form at the 2-mm tip of the proximal stump is expressed as % of the same form's activity in the intact nerve (see Figs 1 and 2). *a*, Chicken, 20S; *b*, rat, 16S; *c*, chicken 11.5S; *d*, rat, 10S.

thus, 6 h after transection, M-form activity had doubled in the chicken and increased 1.5 times in the rat (Fig. 3).

In short, both rat and chicken sciatic nerves contain four molecular forms of AChE—two high molecular weight forms (H and M) and two low molecular weight forms (L_1 and L_2). After transection of the sciatic nerve, only the high molecular weight forms accumulated rapidly at the end of the proximal stump, whereas the low molecular weight forms either remained stationary or accumulated very slowly.

Previous work on dog⁸, cat⁹ and rats^{10,11} showed that after transection or ligation of the sciatic nerve, AChE accumulated at both sides of the lesion, at the speed of rapid axonal transport^{8,9,11}. In dog and cat, it was estimated that approximately 15% of the AChE present in the sciatic nerve was transported fast (10% outward and 5% inward), while the rest was either stationary or slow-moving^{8,9}. In rat, only 3% of the AChE in the sciatic nerve was transported fast¹¹.

Our results therefore indicate (1) that the H form of AChE is present in the intact nerve of rat and chicken and (2) that this and the M form (the other high molecular weight form) move with the rapid phase of axonal transport, whereas the low AChE molecular weight forms L_1 and L_2 , also present in the intact nerve of rat and chicken, either remain stationary or move with the slow phase of axonal transport.

Cholinesterase is associated with the basal lamina at the neuromuscular junction

THE cholinesterase (ChE) of skeletal muscle is concentrated at the neuromuscular junction, where it hydrolyses acetylcholine released from the nerve terminal^{1–3}. In frog muscle treated with a histochemical stain for ChE, enzyme activity is demonstrable at all terminal branches of the neuromuscular junction (Fig. 1*a*), with the reaction product occupying the synaptic cleft between nerve and muscle (Fig. 1*d*)^{1,6}. A particulate enzyme, ChE, was assumed to be integral to the postsynaptic plasma membrane² until Hall and Kelly⁷ showed that mild protease treatment of intact muscles released active ChE into the medium without apparent damage to the plasma membrane. One possibility raised by this result is that ChE is associated with the basal lamina (BL; sometimes called basement membrane) that runs through the synaptic cleft⁸. This idea was supported by the finding that a subunit of ChE from electric organs of fishes and rays has several properties in common with collagen^{9–11}, a protein known to be a principal component of BLs¹². Here, we present direct evidence that junctional ChE is associated with the BL of the synaptic cleft in skeletal muscle.

Our approach was to remove the cellular components of the neuromuscular junction *in vivo* (nerve terminal, Schwann cell, and muscle cell; Fig. 1*d*) leaving behind the BL; we then assayed ChE histochemically. The nerve to the cutaneous pectoris muscle of the frog was cut, causing degeneration of the nerve terminals¹³. A long portion of nerve was removed to maintain denervation, inducing Schwann cell processes to retract from synaptic areas¹³. Muscles were injured mechanically (see Fig. 1 legend and ref. 14), causing disruption of muscle fibres; the damaged cells decomposed, leaving behind the sheaths of BL that surrounded them^{14,15}. Frogs were X-irradiated to prevent regeneration of new muscle within the BL sheaths (ref. 16 and J.R.S., L.M.M. & U.J.M., in preparation). Cellular debris and membrane fragments within the sheaths were phagocytosed^{14,15} and electron microscopy showed that nearly all ($98.3 \pm 0.4\%$; mean \pm s.e.m. of samples from 41 sheaths) of the surface area of the BL was clean by two weeks after the muscle was damaged. Portions of such sheaths are shown in Fig. 1*c*.

When we stained such preparations for ChE^{8,13,17} and examined them under the light microscope, bands of reaction product (Fig. 1*b*) corresponding in size, shape and arrangement to the ChE-outlined terminal arborisations of normal muscle (Fig. 1*a*) were revealed. In addition, the bands had a periodic substructure corresponding to that of the junctional folds (Fig. 1*d*), which are arranged at intervals of approximately $1 \mu\text{m}$ along the endplate⁶. (The periodic variation in staining intensity is particularly prominent after the overlying nerve terminal and Schwann cell processes are removed by denervation, whether the muscle is damaged or not¹³.) Thus, staining for ChE showed that the enzyme was concentrated at junctional sites on the sheaths.

Electron microscopy of the sheaths confirmed that ChE was associated with BL. Reaction product was concentrated in and near the BLs that had occupied the synaptic cleft and projected into junctional folds (Fig. 1*e*). Because reaction product might have obscured remnants of the muscle at junctional sites, we examined preparations not stained for ChE, using the BLs from junctional folds and Schwann cells (Fig. 1*e*) to identify junctional sites on the sheaths¹⁴. Less than 2% of the junctional BL ($1.8 \pm 0.5\%$; $n = 28$) was apposed by fragments of plasma membrane and this is far too little to account for the even pattern of

ChE staining seen light and electron microscopically.

Light microscopic observations provided additional information about the ChE associated with BL. ChE-stained bands on the BL sheaths were fainter than those on normal fibres; it is known that levels of junctional ChE decrease following denervation^{1,2,13,18}. ChE-stained bands on the sheaths were similar in intensity to those on denervated,

but undamaged, fibres in the same preparations; thus, a major fraction of the ChE that survived denervation remained with the BL after the muscle was removed. The intensity of staining was reduced by BW 284C51, a specific inhibitor of 'true' acetylcholinesterase (EC 3.1.1.7) (ref. 2), demonstrating that some, if not all, of the ChE in the BL is acetylcholinesterase.

Fig. 1 *a, b*, Light micrographs of ChE-stained endplates (sites of neuromuscular junctions) on a normal muscle fibre (*a*) and on a BL sheath that survived denervation and muscle damage (*b*). Bars represent 20 μm . *c*, Low-power electron micrograph of a cross section through a BL sheath. Collagen fibrils lie outside the BL and the inside, once occupied by the muscle fibre, is now nearly empty. Bar represents 2 μm . Inset: high-power micrograph of a portion of a BL sheath demonstrates the absence of muscle cell plasma membrane which is normally situated 10–20 nm from the BL. Asterisk is in the lumen of sheath. Bar represents 0.2 μm . *d, e*, Electron micrographs of ChE-stained junctional sites from preparations similar to those shown in *a* and *b*, respectively. Muscle cell (M), Schwann cell process (S), and nerve terminal (N), all present at the normal neuromuscular junction (*d*), disappear following denervation and muscle damage (*e*), leaving behind the BL that surrounded muscle and Schwann cell and projected into junctional folds (arrows). The muscle in *d* was stained lightly for ChE, to avoid obscuring cellular elements. Bars represent 0.5 μm . All experiments were carried out on the cutaneous pectoris muscles of 5-cm male *Rana pipiens*. To prepare BL sheaths, frogs were submitted to the following regimen: On day 1, the nerve to the cutaneous pectoris was cut within 1 mm of the muscle border, and a 2-cm segment of nerve was evulsed. On day 12, pieces were cut from each end of the muscle, leaving behind a central row of 1–1.5-mm long muscle fibre segments, many of which bore endplate sites (details in ref. 14). On day 15, frogs were X-irradiated (250 kV; 15 mA; added filter of 2 mm Al; 65 cm from source to centre of animal; 100 rad min⁻¹; total dose, 1,600 rad). Lead shielding placed over the frog restricted radiation to the thorax. On day 26, animals were killed and muscles were anaesthetised with MS 222. Normal (*a, d*) and damaged (*b, c, e*) muscles were prepared for microscopy as described previously^{6,13}. Ruthenium red was used to stain BL for electron microscopy¹⁴. The histochemical procedure of Karnovsky¹⁷ was used to demonstrate ChE activity^{6,13}. Results similar to those illustrated here were also obtained with muscles that were denervated and damaged on day 1, irradiated on day 3, and fixed 3–5 weeks later.

Thus, at least some of the ChE at the frog neuromuscular junction is very tightly bound to (that is, contained in or connected to) the basal lamina of the synaptic cleft. To our knowledge, this is the first case in which an enzyme has been shown to be associated with the basal lamina of any cell.

We thank Mary Hogan and Linda Yu for assistance, and Dr Henry Kohn for help with X-irradiation. This work was supported by the US Public Health Service and by a Research Fellowship (to L.M.M.) of the Muscular Dystrophy Association.

Effect of calcium ionophore Br-X537A on renin synthesis and release in *Amphiuma means* kidney culture

CALCIUM ions play an important part in stimulus-secretion coupling¹, and in particular have been implicated in the control of renin release from kidneys *in vitro*². The calcium ionophores A23187 and X537A and its derivatives have been used in several studies of the effect of mobilisation and movement of calcium and other divalent ions on biological systems, including mast cells, pancreatic B cells and the neurohypophysis³⁻⁸. X537A and Br-X537A are of interest because they release calcium preferentially from intracellular sites irrespective of the extracellular calcium concentration^{8,9}. In investigating calcium involvement in secretion and the action of ionophores, emphasis has been placed on *in vitro* studies, where the experimental conditions can be closely controlled. We report here the results of experiments on the effect of Br-X537A on the renin levels in *Amphiuma means* kidney in organ culture. This system has the advantages of an isolated tissue, which in addition retains its *in vivo* characteristics for extended periods. We show that Br-X537A has dose-dependent effects on both the synthesis and secretion of renin. These effects apparently represent two quite separate sites of action of the ionophore.

Control of renin secretion is effected through humoral agents, renal sympathetic nerve stimulation, and the intra-renal receptors sensitive to pressure or to ion concentrations¹⁰. Renin release by the kidneys is of fundamental importance in the maintenance of blood pressure and sodium homeostasis. The interpretation of *in vivo* studies of drug action on renin secretion is complicated by the interplay of the control mechanisms¹⁰⁻¹³. To distinguish between direct and indirect actions of drugs on renin release, isolated perfused kidney¹⁴ and kidney slices^{2,15} have been used *in vitro*. These methods avoid the complications

Fig. 1 The renin activity of *A. means* kidney tissue in culture over several days after initiation of culture. Kidneys from two freshly killed animals were immediately removed to culture medium and cut into pieces of average weight 1.5 mg. The pieces were cultured (about 25 mg per 2 ml of medium) in sterile polystyrene universal containers on a roller culture apparatus at 25 °C. Basic culture method was as described by Monnickendam and Balls²⁰. The medium was 50% Eagle's minimum essential medium with 10% foetal calf serum buffered with HEPES (15 mM). Streptomycin sulphate (100 µg ml⁻¹) and benzyl penicillin (100 IU ml⁻¹) were added. Renin activities were measured by radioimmunoassay of angiotensin I generated from exogenous renin substrate, using a method based on that of Cohen *et al.*²¹ and Haber *et al.*²². The renin activities are expressed as the amount of angiotensin I generated per mg of tissue (wet weight). The bars represent s.e.m., and the number of cultures for each point was either 7 or 8, except for day 0 (fresh tissue) where renin activities were measured in tissue equivalent to three cultures. Each trace shows the renin activity in tissue from a single kidney: A1 and A2 referring to the two kidneys from one animal (measurements made from day 0 to day 5); B1 and B2 to kidneys from the second animal (day 3 to day 7).

of haemodynamic and humoral factors. However, it is known that tissue slices from adult mammalian kidneys lose their normal structure and function in quite short periods ranging from 20 s to 3 d, depending on the experimental conditions¹⁶⁻¹⁹.

By contrast, many amphibian tissues in organ culture maintain their structure and biochemical functions for periods of up to 5 weeks²⁰. We have shown that *A. means* kidney in culture maintains its renin content for several days (see Fig. 1). This system is therefore useful for studying the long- and short-term effects of drugs without the complications of changes in haemodynamic and sympathetic nervous activity.

As shown in Fig. 1, after an initial drop in tissue renin activity at the start of the culture period, the renin activity fluctuates with time. Cultures from one kidney behave quantitatively in the same way. Tissue from the second kidney of the same animal may show quite different fluctuations. In studying the effect of the ionophore we have, therefore, related renin activities in the tissue and culture medium at given times to those of controls using tissue from the same kidney.

Table 1 Effect of Br-X537A and puromycin on renin activities in *A. means* kidney and culture media

Treatment	Tissue	Renin activity (pg angiotensin I mg tissue ⁻¹ h ⁻¹) Medium	Total
None (control)	160.7 ± 3.0 (9)	9.7 ± 0.9 (9)	170.4 ± 3.4
Br-X537A 2.12 µg ml ⁻¹	357.4 ± 8.2 (8)*	16.9 ± 2.7 (8)*	374.3 ± 9.3*
None (control)	83.9 ± 2.4 (6)	15.0 ± 1.8 (6)	98.9 ± 3.3
Br-X537A 11.5 µg ml ⁻¹	157.0 ± 4.5 (6)*	40.0 ± 1.9 (6)*	197.1 ± 3.3*
Puromycin 0.25 mM	82.8 ± 2.4 (7)	11.6 ± 1.2 (7)	94.4 ± 2.8
None (control)	154.4 ± 12.7 (5)	15.3 ± 1.6 (5)	169.8 ± 14.2
Br-X537A 20.5 µg	129.8 ± 3.8 (5)	34.4 ± 5.0 (5)†	164.2 ± 6.2
None (control)	184.3 ± 2.5 (6)	19.1 ± 1.2 (6)	203.4 ± 2.9
Puromycin 0.25 mM + Br-X537A 11.5 µg ml ⁻¹	160.0 ± 2.8 (6)*	22.0 ± 3.0 (6)	181.7 ± 5.6†

Results are expressed as mean ± s.e.m. with number of cultures in parenthesis. The culture medium and conditions, and method of renin assay were as described in Fig. 1 and the text.

* $P < 0.001$, in comparison between treated and control values in the same experiment.

† $P < 0.01$.

For drug treatments fresh kidney tissue was cultured at 25 °C for 20–24 h. The medium was then changed to either fresh medium (controls) or to fresh medium containing the drugs. After treatment for 24 h the kidney pieces were removed, rapidly blotted, weighed, frozen and kept at –20 °C until assayed for renin activity. Media containing the ionophore were prepared from solutions of the drug in dimethyl sulphoxide. In control cultures dimethyl sulphoxide was added to give the same concentration as in the treated cultures. The concentration of the solvent never exceeded 0.5% v/v. Lactate dehydrogenase (LDH) activity in the medium was measured to check for nonspecific leakage of cell contents. The amount of LDH in the medium was less than 0.5% of that measured in the tissue.

The effects of Br-X537A and puromycin on renin activity are shown in Table 1 and Fig. 2. Over 24 h puromycin alone has no effect. The ionophore gives two dose-dependent effects on renin levels. The first effect is on renin synthesis. There is a stimulation of total (tissue + medium) renin

activity at low ionophore concentrations, and this effect is progressively inhibited as the ionophore concentration is increased. That this is due to enhanced renin synthesis and not to some other action of the ionophore is indicated by the observation that the presence of both puromycin and ionophore (11.5 µg ml⁻¹) together causes only a small decrease in the total renin activity. The second dose-dependent effect is on renin release. In order to distinguish the effect on renin release as distinct from synthesis, we can express the medium renin activity as a fraction of the total renin activity present, f . Then to take into account the variability between different kidneys, f is normalised to the control value (see Fig. 2 insert). Then it is apparent, that puromycin has no significant effect on renin release and, as has been observed by other workers using the neurohypophysis⁸, the amount of hormone released increases with ionophore concentration. However, the validity of interpreting the results quantitatively this way depends on all the tissue renin being equally available for release.

The secretagogue^{4,8}, pseudofertilisation²³, and cardiovascular⁶ actions of X537A and Br-X537A are usually interpreted as being mediated by mobilisation of Ca²⁺ ions and/or catecholamines. We have been unable to show a significant effect of isoprenaline or adrenaline on renin levels in *A. means* kidney *in vitro* over the time scale of the present experiments (data not shown); this suggests that intracellular Ca²⁺ activities are critical in determining renin synthesis, in a manner reminiscent of steroidogenesis in the adrenal cortex²⁴, and synthesis of hormones in the pituitary²⁵. We have been able to demonstrate the two separate actions of Br-X537A on renin levels (synthesis and secretion), because we have used an *in vitro* kidney system that retains its renin for extended periods.

This work was supported by a grant from the East Anglian Hospital Board. We thank Dr I. Atwater and Professor E. Rojas for useful discussions, Dr M. Balls for help in initiating our work on kidney organ culture, and Hoffman-LaRoche for Br-X537A.

Fig. 1 Stimulation of aldosterone production by angiotensin II in glomerulosa cells from control rats (\square) and rats receiving angiotensin II infusion for 36 h (\circ). Isolated glomerulosa cells were prepared from adrenal capsules of 50 animals in each of the control and angiotensin-infused groups.

Angiotensin II regulates its receptor sites in the adrenal glomerulosa zone

DURING sodium deficiency, adrenocortical sensitivity to angiotensin II is increased in several species¹⁻³. Following acute sodium restriction in the rat, adrenal receptor sites for angiotensin II show increased concentration and binding affinity, and aldosterone responses to angiotensin II are increased both *in vivo* and *in vitro*⁴. Since circulating renin and angiotensin II levels are elevated during sodium deficiency^{2,3}, these changes in the adrenal gland could be mediated by the trophic action of angiotensin II on the zona glomerulosa. Increased levels of catecholamines and trophic peptide hormones, such as luteinising hormone, have been shown to cause receptor loss and desensitisation of specific responses in their respective target cells⁵⁻⁷. It is possible, however, that physiological elevations of blood angiotensin II concentration could exert the opposite effect in the adrenal zona glomerulosa, leading to enhanced receptor function and contributing to the increased adrenal sensitivity during sodium restriction. To determine whether angiotensin II modulates its own receptors as well as the aldosterone secretory response, we examined angiotensin II receptors and aldosterone production in the zona glomerulosa of rats following elevation of circulating angiotensin II levels. These studies have provided evidence that angiotensin II can regulate its own receptor sites as well as steroidogenic responsiveness in the adrenal glomerulosa cell.

Isolated zona glomerulosa cells and membrane-rich particles were prepared from adrenal glands of adult rats as described previously⁸. Circulating angiotensin II levels were increased by implanting Alzet osmotic minipumps (Alza Corporation, Palo Alto) intraperitoneally for periods of 36 h-6 d, to give sustained release of synthetic [Asp¹, Ile³]angiotensin II (Beckman Instruments, Inc. Palo Alto), at a rate of 50 ng min⁻¹. The control rats were implanted similarly with empty plastic tubing for equivalent periods. Assay of adrenal receptors by binding of ¹²⁵I-angiotensin II, and measurement of aldosterone in plasma and incubation media, were carried out as described previously^{8,9}.

Plasma aldosterone concentrations were markedly increased from 9.8 ± 2.5 ($n = 12$) to 26.9 ± 5.8 ng per 100 ml ($n = 13$), following infusion of angiotensin II for 36 h-6 d ($P < 0.001$). Angiotensin II infusion was also followed by enhancement of basal and angiotensin-stimulated aldosterone production in isolated glomerulosa cells (Fig. 1). After 36 h of infusion, the maximum aldosterone response *in vitro* was increased from 9.2 ± 0.4 to 26.0 ± 1.3 ng ml⁻¹

($P < 0.001$). The increased maximum response to angiotensin II *in vitro* was not accompanied by a change in sensitivity to the peptide, as reflected in the angiotensin concentration required to achieve a half-maximum aldosterone response. This rapid and marked change in adrenal responsiveness was accompanied by commensurate changes in the concentration of angiotensin II receptors in the adrenal glomerulosa cell (Fig. 2). A significant increase in the number of angiotensin II receptors was observed after 36 h of angiotensin II infusion, with no change in the association constant of the angiotensin II receptor. Similar increases in the angiotensin II binding capacity (that is, in receptor sites) were observed in adrenal subcellular particles after 36 h (Fig. 3). Such changes were observed for up to 6 d of infusion, whereas receptor affinity was not significantly altered (Table 1).

The rate of angiotensin II infusion used in these studies (50 ng min⁻¹) was accompanied by a slight increase in sodium excretion by the experimental animals. This sodium loss may possibly contribute to changes in angiotensin II receptors and adrenal responses, albeit by an as yet undefined mechanism. The same effects were also observed following infusion of angiotensin II at a rate (20 ng min⁻¹) that had no detectable influence on sodium excretion, however, thus emphasising the ability of the octapeptide to act directly on adrenal receptors and steroidogenic responses.

This study has demonstrated that infusion of angiotensin II causes rapid and significant increases in both angiotensin II receptors and angiotensin-induced responses in the adrenal glomerulosa cells. In contrast, exposure of other target tissues to high hormone concentrations frequently results in reduction of receptor sites and biological effects of the regulatory hormone. Such 'desensitisation' phenomena have been found for luteinising hormone and catecholamines⁵⁻⁷. Other peptide hormones such as insulin, growth hormone, and thyrotropin-releasing hormone decrease their own receptors¹⁰⁻¹², whereas high circulating prolactin concentrations produced by oestrogen treatment are believed to increase the hepatic prolactin receptor¹³. In tissues in which receptors are decreased by elevations of the homologous hormone, an increase in hormone receptors would be expected when the circulating hormone is decreased. Accordingly, both thyrocalcitonin receptors and

Table 1 Concentration and binding affinity of angiotensin II receptors in adrenal of control and angiotensin II-infused rats

Duration of infusion (d)	Control		After angiotensin II infusion	
	Concentration (fmol mg ⁻¹)	K _a (× 10 ⁹ M ⁻¹)	Concentration (fmol mg ⁻¹)	K _a (× 10 ⁹ M ⁻¹)
1.5	1,188 ± 40	0.53 ± 0.04	1,766 ± 109	0.56 ± 0.09
3.5	1,697 ± 120	0.84 ± 0.13	2,463 ± 263	0.69 ± 0.12
3.5	1,288 ± 39	1.79 ± 0.03	1,629 ± 74	0.88 ± 0.05
6.5	1,160 ± 52	0.76 ± 0.04	1,911 ± 123	0.61 ± 0.03

Angiotensin II receptor concentrations for all experiments significantly increased ($P < 0.02$) from $1,333 \pm 124$ to $1,943 \pm 183$ (mean ± s.e.) following angiotensin II infusion. Each of the four experiments was performed on adrenal particles prepared from 15 rats in the control and angiotensin-infused groups.

uterine angiotensin II receptors are increased by the absence of the regulatory hormone^{14,15}. The adrenal angiotensin II receptor, however, seems to be regulated in the opposite manner. Thus, angiotensin II receptors in the rat adrenal are reduced after nephrectomy¹⁶ and aldosterone responses of the human zona glomerulosa are reduced following the removal of endogenous angiotensin II by nephrectomy and restored after renal allografts¹⁷. Conversely, sodium restriction, which is associated with increased circulating angiotensin II levels, increases angiotensin II binding sites and the sensitivity and magnitude of the aldosterone response^{2-14,18}.

Administration of pharmacological doses of angiotensin II has been shown to produce a decrease in adrenal receptor sites in nephrectomised rats¹⁸. Such depletion of peptide receptors probably occurs in all target cells after excessive degrees of receptor occupancy, and may bear little relevance to the physiological modulation of target cell functions by normal variations in circulating hormone concentration. In contrast, the administration of nanogram quantities of angiotensin II in the present study was accompanied by a rise in specific adrenal receptors, in keeping with the enhanced aldosterone production seen *in vitro* and *in vivo* after angiotensin infusion. It should be noted that the level of plasma aldosterone produced by angiotensin II infusion was less than that observed during similar periods of sodium deficiency, namely 69.2 ± 7.2 ng per 100 ml after 4 d. This

Fig. 2 Saturation curves of angiotensin II binding data derived with adrenal glomerulosa cells from control rats (□) and rats receiving angiotensin II infusion from 36 h (○). Binding analysis was on the cell preparations used for the aldosterone dose-response studies shown in Fig. 1.**Fig. 3** Scatchard plots of angiotensin II binding in adrenal glomerulosa 30,000g particulate fraction from control rats (□) and rats receiving angiotensin II infusion for 36 h (○). Each set of binding data was derived from adrenal particles prepared from 15 control and 15 angiotensin-infused animals.

difference could reflect the need for a pulsatile or episodic pattern of increased angiotensin II secretion to produce the maximum trophic action on zona glomerulosa cells. The presence of diurnal variation and episodic secretion of renin is well established in man, and pulsatile change may form an important component of the modulating effect of angiotensin II on adrenal glomerulosa function and aldosterone secretion.

We suggest that the direct regulatory effect of angiotensin II on the zona glomerulosa is a major factor in the increased responsiveness of the adrenal cortex during sodium restriction. This view is consistent with earlier studies which showed the administration of renin increases adrenocortical sensitivity to angiotensin II in the dog¹⁹, and with the recent finding that prolonged infusion of angiotensin II in man similarly increases the sensitivity of the adrenal cortex²⁰. Such changes are also accompanied by an increase in ACTH-induced aldosterone responses, indicating a generalised enhancement of the aldosterone biosynthetic pathway^{19,21} that is consistent with a trophic action of angiotensin II on the adrenal gland. In conjunction with these observations, our findings of angiotensin II receptor induction and correspondingly increased steroid responses provide direct evidence that angiotensin II exerts a trophic action on cells of the zona glomerulosa, in addition to its acute regulatory effects on aldosterone secretion.

Evidence for a long Leu-enkephalin striopallidal pathway in rat brain

THE pentapeptides leucine (Leu-) enkephalin and methionine (Met-) enkephalin were isolated from brain and shown to be endogenous opiates¹. These peptides bind to the brain opiate receptor², and their biological actions are blocked by the morphine antagonist naloxone³. The availability of synthetic enkephalins has led to the development of radioimmunoassays (refs 2, 4, and R. Miller, personal communication) and immunohistochemical techniques. Preliminary immunohistochemical studies^{5,6} have shown the distribution of enkephalin-containing fibres to coincide with the regional distribution of opiate receptors as determined by biochemical techniques and autoradiography⁶⁻⁸. The highest density of enkephalin-positive fibres^{8,9} was located in the globus pallidus. We have now confirmed the presence of enkephalin-immunoreactive fibres in the globus pallidus, and using specific lesions have shown this immunoreactivity to be abolished by destruction of the neural connections between the globus pallidus and the caudoputamen.

The visualisation of the Leu-enkephalin-immunoreactive fibres in the brain tissue was carried out using the indirect fluorescent immunohistochemical techniques first described by Coons and Kaplan⁹ with a Leu-enkephalin antiserum from rabbit and anti-rabbit IgG fluorescein conjugated immunoglobulin (Wellcome). Rat brains were fixed by intracardiac perfusion with 4% cold paraformaldehyde in 0.1 M buffer phosphate and processed as described by Hökfelt *et al.*¹⁰. Cryostat sections 10-µm thick were used for immunocytochemistry. The exact location and extent of each lesion was determined from Nissl-stained sections. Leu-enkephalin antiserum was raised in the rabbit by Dr R. Miller of Burroughs Wellcome. The Leu-enkephalin antiserum did not cross-react with β -lipotropin or adrenocorticotrophic hormone (ACTH), and the cross-reactivity with Met-enkephalin was 1% and with β -endorphin < 0.01%. The specific immunofluorescence in the globus pallidus and other regions was not observed if the Leu-enkephalin antiserum was previously absorbed with Leu-enkephalin (200 µg ml⁻¹). Light microscopy at high magnification showed the immunoreactivity in the globus pallidus to form a dense mesh of intensely fluorescent elements. The lack of immunoreactive elements in the caudoputamen and the abundance in the globus pallidus causes a sharp delineation of the border between caudoputamen and the globus pallidus.

Isolation of the globus pallidus from the neighbouring caudoputamen by a knife-cut lesion within the caudoputamen (Fig. 1, lesion 1) caused an almost complete depletion of Leu-enkephalin immunofluorescence from the ipsilateral globus pallidus (Fig. 2a, b). In 10 animals, the magnitude of this depletion was related to the extent of the lesion in the caudoputamen determined from alternate Nissl-stained sections. Knife cuts limited to the rostral pole of the caudoputamen (Fig. 1, lesion 2) produced a depletion of enkephalin immunoreactivity restricted to the medial and rostral portions of the globus pallidus. This observation suggests a possible topographical arrangement of the enkephalin-containing fibres in the caudoputamen-globus pallidus pathway.

The view that the Leu-enkephalin might be present in the processes of striatal neurones was reinforced by the appearance

Fig. 1 Schematic representation of a horizontal section of the rat brain. CX, cortex; CP, caudoputamen; GP, globus pallidus; A, nucleus accumbens; ac, anterior commissure; st, nucleus interstitialis of the stria terminalis; SN, substantia nigra. 1, Knife cut isolating the caudoputamen from globus pallidus; 2, knife cut in the rostral pole of the caudoputamen; 3, cerebral cortex knife undercut; 4, brain hemisection; 5, electrolytic lesion of the medial forebrain bundle; 6, intranigral injection of 6-hydroxydopamine. Lesions 1-4 were performed with a stereotactically-guided microknife. Survival time for all procedures was 5-8 d.

of bundles of fluorescent beaded fibres on the striatal side of the knife cuts (Fig. 3). These fluorescent fibres were only seen on the lesioned side, running radially through the striatum towards the globus pallidus. When consecutive sections were incubated with non-immune serum or anti-enkephalin serum pre-absorbed with Leu-enkephalin (200 µg ml⁻¹) the accumulation of fluorescent material proximal to the lesion was not observed. The build-up of enkephalin immunofluorescence observed here is similar to that seen with substance P after dorsal root lesions¹⁰ or knife cuts in the central nervous system¹¹.

Stereotaxic undercutting of the cerebral cortex with a microknife (Fig. 1, lesion 3) did not produce any noticeable change in the intensity or pattern of the pallidal immunofluorescence compared with the contralateral untreated side. Stereotaxic injections of 6-hydroxydopamine (8 µg in 2 µl given over 4 min) into the substantia nigra which in parallel experiments resulted in a 60-70% fall in striatal dopamine content, electrolytic lesions of the medial forebrain bundle (2 mA, 20 s), and stereotaxic knife-cut hemisections at the middle-hypothalamic level, all failed to change the pattern of Leu-enkephalin immunoreactivity in the globus pallidus (Fig. 1, lesions 4-6).

These findings are in agreement with recent biochemical observations which show that the radioimmunoassayable enkephalin content of the basal ganglia does not change after cortical ablation¹⁴, but decreases by 50% following cell body destruction induced by intrastriatal injection of kainic acid⁴. They are also in agreement with the reported appearance of enkephalin immunoreactive cell bodies in the caudoputamen following inhibition of axonal transport by colchicine¹⁵.

Our results suggest that the Leu-enkephalin-containing nerve fibres in the pallidum do not belong to an intrinsic neuronal circuit but instead to a striopallidal pathway. Such a connection between the two basal ganglia nuclei is consistent with classical

Fig. 2 *a*, Leu-enkephalin immunofluorescence in the globus pallidus (GP). Note the lack of immunoreactivity in caudoputamen. Horizontal section, untreated side. *b*, Ablation of Leu-enkephalin immunofluorescence in the globus pallidus following de-afferentation from the caudoputamen (contralateral to *a*). Scale bar, 225 μ m.

neuroanatomical studies which show neurones in the caudoputamen to branch extensively within the globus pallidus^{12,13}. The role of this 'long enkephalinergic' striopallidal pathway in extrapyramidal function and disease, remain to be established.

We thank Drs L. L. Iversen and J. S. Kelly for reading this manuscript, Mrs Angie Nelson for technical assistance, and Mr Chris Rayner and Mr George Marshall for their cooperation.

Evidence for symmetry in the phytochrome subunit

PHYTOCHROME is a chromoprotein that has been shown to initiate and control major developmental responses of plants to light¹. It has two spectrally different forms that can be reversibly interconverted by light, as indicated:

The spectral properties of phytochrome are sensitive to changes in the microenvironment of the covalently bound chromophore(s). Relatively mild denaturing treatments, such as incubation at 25 °C for over an hour² and dehydration³, result in a significant loss of photoreversibility. In view of this susceptibility to spectral denaturation, it is remarkable that phytochrome can be proteolytically degraded to a molecular weight (MW) of 60,000, or half its native subunit size, without exhibiting any loss of photoreversibility or even any blue shift in its peak absorbance as Pr⁴. The additional fact that further proteolysis of phytochrome to 40,000 MW drastically reduces photoreversibility⁵ suggests that the 60,000 MW fragment has a sequence and configuration that are both sufficient and necessary to preserve photoreversibility. It is not clear whether this fragment is the product of one or more centrally located

cleavages of the native subunit to yield two pieces of MW near 60,000 per native subunit or whether it is the product of extensive proteolysis which yields a single 60,000 MW fragment per native subunit. We have compared the amino acid composition and the peptide map of the proteolytically-derived 60,000 MW fragment with those of the native 120,000 MW subunit. Our results strongly support the conclusion that the native 120,000 MW subunit is composed of two halves with nearly identical sequences.

To assure maximum purity, phytochrome was isolated from single bands on sodium dodecyl sulphate (SDS) gels after the preparative electrophoresis method of Stephens⁶. The samples used for the preparative electrophoresis were 70-80% pure and were isolated from etiolated oats by the method of Roux *et al.*⁷. By varying the extraction conditions this method can be used to produce both native phytochrome with intact 120,000 MW subunits and also the 60,000 MW fragment of phytochrome⁷. The MW of the smaller fragment was confirmed to be 60,000 by chromatography on a calibrated molecular sieve gel before electrophoresis on SDS gels. After the preparative electrophoresis, the purity and molecular weight of the samples were confirmed by re-electrophoresing aliquots of them on SDS gels. In all cases, 10 µg samples gave single bands at either 60,000 or 120,000 MW, indicating over 95% purity.

Table 1 compares the amino acid composition of the pure 60,000 and 120,000 MW phytochrome. This is the first report of the amino acid composition of the native phytochrome subunit. One analysis of each molecular weight species is shown. A second set of analyses on different phytochrome preparations that were also purified by the electrophoresis method gave identical results. To show that the preparative electrophoresis method of isolation does not produce composition artefacts and to further indicate the reproducibility of the results, the composition of 60,000 MW phytochrome isolated by standard chromatographic methods⁸ is given alongside of the electrophoretically isolated phytochrome.

The data in Table 1 reflect the composition values in mol % after subtracting the background values of a blank. This background contamination level was determined by amino acid analysis of material extracted from blank areas of the preparative gels. The reproducible contamination level was low but measurable and typical of that reported by others using the same technique⁹. The standard error limits for the final extrapolated values given are ± 0.2 mol % for all residues except Gly and Asp, where the error limits are about ± 1.0 and ± 0.5 mol % respectively. Thus the 120,000 and 60,000 MW peptides have statistically the same compositions at six residues (Lys, His, Arg, Ser, Met, and Ile). The differences at the other residues range from barely significant (Cys, Phe, Thr: 0.3 mol %) to 1.6 mol % for Gly.

The composition data are consistent with the hypothesis that the isolated 60,000 MW fragments were a heterogeneous mixture of two dissimilar halves of the native subunit. But they also suggest the possibility that the subunit may be composed of two nearly identical 60,000 MW regions. To distinguish which of these conclusions was more likely, tryptic peptide maps of the two phytochrome species were prepared. If the native subunit had little or no internal symmetry, then, ideally, one would expect to identify a number of tryptic peptides equal to the number of Lys and Arg residues in the native subunit plus one. On the other hand, the greater the symmetry, the fewer the number of different peptides that would separate on the map, with the lower limit being the number of peptides that were separable on the map of the 60,000 MW fragment. From the composition data, there were 59 lysines and 49 arginines per 120,000 MW subunit and 30 Lys and 24 Arg in the 60,000 MW fragment.

Complete tryptic digests of electrophoretically pure 120,000 and 60,000 MW phytochrome were prepared and chromatographed as described in the legend to Fig. 1. Two maps of two separately purified samples were made for both the intact

Fig. 1 *a*, Peptide mapping on thin-layer Silica G plates was patterned after a procedure by Stephens¹⁰. The isolated protein was subjected to complete tryptic digestion using a protein to DCC-trypsin ratio of 100:1 (w/w) for 24 h at 25 °C in 1% (NH₄)₂CO₃. The reaction was terminated by addition of several drops of glacial acetic acid followed by lyophilisation with three washes of distilled water. The digests were chromatographed on 20 × 20 cm Silica G plates in butanol-acetic acid-water (80:20:20) and air-dried overnight. High voltage electrophoresis in a perpendicular direction was performed on a Savant flat bed high voltage electrophoresis unit at 1,000 V for 105 min using pyridine-acetic acid-water (100:8:397), pH 6.5, solvent. The plates were oven-dried for 1 h at 110 °C. The final map was visualised with ultraviolet light after spraying with fluorescamine (0.025% in acetone). The fluorescing map was photographically documented using Kodak contrast process pan film. This figure represents a composite of six different peptide maps; three of the 120,000 MW subunit and three of the 60,000 MW fragment. The open circles denote those peptides common to both phytochrome species (55). Shaded circles denote peptides seen only on maps of the 120,000 MW subunit. Cross-hatched circles denote peptides only on maps of the 60,000 MW fragment. *b*, This is the same composite as (*a*) but the intensity of fluorescence is recorded. Three concentric circles denotes bright, two concentric circles denotes moderate, and a single circle denotes dim intensity.

subunit and its fragment. The peptide 'fingerprints' were visualised after fluorescamine treatment by their fluorescence under ultraviolet light. From photographic prints of the maps, *x-y* coordinates and relative intensity values were assigned to each peptide spot, and from these assignments the composite map shown in Fig. 1 was drawn.

The composite map illustrates that we were able to identify only 60 different peptides on the map of the 120,000 MW subunit, and of these 55 were in the same relative position and had

the same relative intensity as distinct peptide spots on the map of 60,000 MW phytochrome. As shown in Fig. 1, we identified 63 peptides on the map of the 60,000 dalton fragment, eight more than the ideal maximum predicted from the Lys and Arg content of the fragment. This anomaly can probably be ascribed to the likely size microheterogeneity of the 60,000 MW preparation. Such heterogeneity would be expected as this fragment is produced by the action of a variety of endogenous oat proteases¹⁰, none of which, presumably, are trypsin. Direct evidence of the heterogeneity of 60,000 MW phytochrome was provided by Rice and Briggs¹¹, who identified four different N-terminal amino acids in a preparation which was homogeneous in SDS gel analysis. The fact that two of the peptides unique to the 60,000 MW fragment only dimly fluoresce suggests that they are minor components of the population and further supports the hypothesis of microheterogeneity within the population of these fragments.

To rule out the possibility that some of the brighter spots represented multiple peptides whose fluorescent intensity masked their resolution as separate spots, we ran additional maps on reduced quantities of tryptic digests. Though these maps gave greater resolution of the brighter spots, they did not reveal any new spots. To demonstrate that our chromatography conditions would allow the separation of more spots, if they were present, we ran maps of phytochrome samples which were only 80% pure. We were able to identify up to 12 new spots on these maps, in addition to those depicted in Fig. 1.

The data presented above strongly support the hypothesis that the native subunit of phytochrome has extensive regions of internal symmetry in its primary structure. Because the compared amino acid compositions and peptide maps are not identical, it is unlikely that the symmetry is complete. These data do not show whether the symmetry is tandem or bilateral, nor do they reveal whether the symmetry extends to the number and position of the chromophore(s) of phytochrome. Our results contradict the conclusion inferred from immunochemical evidence that the 60,000 MW fragment of phytochrome bears little resemblance to the other half of the native subunit¹². But these data do not argue against the conclusion that the native subunit is, in fact, of MW 120,000. The evidence for the latter¹¹ seems incontrovertible.

It is not known whether the extensive sequence duplication in phytochrome has any functional significance. Information on this point may come from experiments in progress to compare the competence of 60,000 and 120,000 MW phytochrome to affect the properties of native¹³ and model¹⁴ membranes.

Neutron diffraction studies on selectively deuterated phospholipid bilayers

NEUTRON diffraction combined with the use of selectively deuterated lipids can provide detailed information on the molecular structure of membranes. Because of the large difference between the coherent scattering length of hydrogen (-3.74 fermis) and deuterium (6.67 fermis) the deuterated membrane segments show up as intense peaks in the neutron density profile and can thus easily be located in the membrane¹⁻³. We have applied this method to bilayer membranes of 1,2-dipalmitoyl-*sn*-glycero-3-phosphocholine (DPPC), selectively deuterated at 12 different positions in the polar head group and the hydrocarbon chains. We report here that the mean position of the deuterated segments within the membrane can be determined in most cases to a precision of better than ± 1 Å. The average orientation of the phosphocholine group in the gel state as well as in the liquid crystalline state is almost parallel to the membrane surface. In the gel state the two hydrocarbon chains are out of step by about 1.8 Å, and water penetrates up to the glycerol backbone of the lipid molecules.

The selectively deuterated DPPC molecules were synthesised as described elsewhere^{4,5}. The measurements were carried out at low-water content (5-6 weight % water; 20°C) and at high-water content (25 wt % water; 28°C , 38°C , and 50°C). At low-water content the multilayered system was orientated on quartz slides and the Bragg reflections were measured in so-called $\theta-2\theta$ scans¹ on the D16 diffractometer at Institut Laue-Langevin (ILL). The mosaic spread measured for these samples had a half width at half height of about 12° . Figure 1a, b shows the first 10 lamellar orders for DPPC deuterated in both chains at the fifth carbon atom for the first sample and at the 15th carbon atom for the second. Only the first orders are very strong whereas the higher orders are so weak that most of them can hardly be seen in this plot. The quite dramatic differences in the ratios of the peaks on changing the label position indicate the sensitivity of the method. For the high water content samples, the lipid mixed with 25% water was sealed into cells with quartz windows. The resulting diffraction pattern consists of Debye-Scherrer rings which were observed with a two-dimensional position sensitive detector⁶ (the D11 camera at ILL).

Fig. 1 Diffraction pattern of the lamellar reflections of DPPC multilayers. *a, b*, 10 orders from a $\theta-2\theta$ scan of two DPPC samples deuterated at the C15 (*a*) and C5 (*b*) position respectively. Each sample was orientated on quartz slides (water content 5-6% wt H_2O , 20°C , $d = 57.4$ Å, $\lambda = 4.43$ Å, θ = Bragg angle). *c*, Profiles of three Debye-Scherrer rings of powder samples deuterated at C_{β} , C_4 and C_{14} position respectively, as measured on D11 at ILL (water content 25% wt H_2O , 28°C , $d = 62.5$ Å, $\lambda = 6.26$ Å, $s = 2 \sin\theta/\lambda$). In order not to complicate the picture the three curves were shifted with respect to each other.

Because of inherent disorder in these samples the intensities of the diffraction orders become quite rapidly smaller with increasing scattering angle and it was difficult to observe more than four reflections. The first three orders, shown in Fig. 1c, illustrate the large changes in the ratios of the reflections when different segments of the lipid are deuterated. From these intensities, after appropriate corrections, the structure factors have been derived. Since the structure is centrosymmetric the phase problem is reduced to the choice between 0 and π . Compared to X-ray analysis, neutron diffraction offers several advantages for phasing and also for scaling the individual samples. Thus all the strong

orders are phased by using the isomorphous replacement technique where H_2O in the bilayer is successively exchanged against D_2O (refs 1–3).

Figure 2a and b contains the density profiles of DPPC/ H_2O mixtures labelled at the C15 and C5 positions and correspond to the diffraction patterns of Fig. 1a, b. Figure 2c is the difference profile of the C5-labelled lipid in D_2O and in H_2O showing the water distribution.

In principle, it is possible to obtain the position of the deuterium label directly from the density profiles; however, this procedure introduces some uncertainties because of Fourier series truncation errors. In addition, it would have been very time consuming to determine higher orders precisely for all the samples in different conditions (H_2O – D_2O –water content, temperature) as in most cases these orders are weak. Therefore we restrict ourselves to measuring only the strong reflections and to calculating the label positions in reciprocal space by the following procedure. After scaling and phasing each set of structure factors, the appropriate differences between pairs of different sets were derived. These difference sets were then used in a model fitting calculation in which the label distribution was assumed to be gaussian. Mean positions for the labels were therefore obtained with all 12 data sets contributing in each case.

Table 1 summarises the mean positions for the various deuterated segments of DPPC bilayers; the DPPC structure is given in Fig. 3. The distances are measured from the centre of the bilayer. The thermodynamic state of the bilayer is designated according to Luzzati and Tardieu^{7,8}. At low-water content (5–6 wt %) and 20 °C the bilayer is in the gel state and from the separation of the C2 segments of the fatty acyl chains the thickness of the hydrocarbon region is found to be 37.6 ± 2 Å. This result represents an average value, however, since it has been obtained from an experiment in which both fatty acyl chains were deuterated. Labelling the two chains individually reveals different distances for the two C2 segments. The C2(2) segment of fatty acyl chain 2 (attached at the C2 atom of the glycerol backbone) is about 1.9 Å further away from the centre of the bilayer than the corresponding C2(1) segment in the adjacent fatty acyl chain (attached at the C1 atom of the glycerol backbone). Furthermore, model calculations on the density profile of C15-labelled DPPC (Fig. 2a) also show that the two deuterated C15 segments of the same lipid molecule are separated in the bilayer by about 1.8 Å. These results then prove that the two hydrocarbon chains of DPPC in the membrane are out of step by about 1.5 carbon–carbon bonds with fatty acyl chain 2 shifted closer to the membrane surface. A similar finding has been reported for single crystals of dilauroyl-phosphatidylethanolamine⁹. On the other hand, the three segments of the choline moiety (C_α , C_β , C_γ) are positioned at almost

Fig. 2 6-Å resolution scattering length density profiles of DPPC at low-water content (5–6%) and 20 °C. a, deuterated at the C15 position; b, at the C5 position; c, water distribution determined from a difference profile of C5 in D_2O and H_2O . The lamellar spacing was 57.4 Å.

the same distance from the centre of the bilayer, which proves unambiguously that the phosphocholine dipole is orientated parallel to the membrane surface. This is further substantiated by comparing the experimental results with corresponding distances measured from a space-filling molecular model of DPPC (column 3). In this model the two fatty acyl chains were assumed to be out of step by 1.8 Å. Furthermore, in order to comply with the X-ray measurements⁸ both chains were tilted by 16° with respect to the bilayer normal. The choline head groups were either aligned parallel (column 3a) or extended perpendicular (column 3b) to the membrane surface. Table 1 shows that only the parallel head group orientation is in agreement with the experimental findings.

The last three columns represent the results at high-water content. In the L_β phase an increase in the water content from 5 wt % to 25 wt % changes the tilt angle of the hydrocarbon chains

*The three bilayer phases were also investigated by means of X-ray diffraction. The various patterns agree with those published by Janiak *et al.*¹⁰.

from 16° to 30° (ref. 10), leading to a concomitant reduction of the projected length of the hydrocarbon chains by 1.75 Å. This is also reflected in the position of the deuterium labels which in the high-water content L_{β} phase are shifted closer to the bilayer interior (column 4). At the pre-transition temperature of 35 °C the bilayer structure changes from L_{β} to P_{β} . According to Janiak *et al.*¹⁰ the P_{β} phase is characterised by a two-dimensional lattice with a rippled bilayer. The label positions as seen by neutron diffraction are almost the same in the L_{β} and P_{β} phase (column 5), however, and we therefore conclude that this effect produces only minor structural changes in the projection normal to the bilayer plane. It could be argued that the observed intensities of the I (h, 0) rings also contain contributions from the weak I (h, k) reflections which

Fig. 3 Structure of DPPC molecule showing labelling positions (see Table 1).

would reduce the accuracy of our structure factors. Analysing the densitometer tracing of the P_{β} phase X-ray picture we can estimate a maximum error of 6% in the structure factors if three orders of I (h, k) are superimposed on one I (h, 0) reflection. This error does not seriously affect the determination of the mean label positions.

At 50 °C the DPPC bilayers are in the liquid crystalline state with disordered hydrocarbon chains. This is evidenced by a remarkable contraction of the DPPC bilayer by about 6–8 Å, but again the three segments of the choline moiety exhibit almost the same distance from the centre of the bilayer. Thus regardless of whether the membrane is in the gel or in the liquid crystalline state and independent of the water content the phosphocholine dipole is always parallel to the plane of the membrane. We are at present investigating the effects of ions on the head group structure.

We thank Dr H. Stuhmann for helping us to start this work and Dr V. Luzzati for his support. We thank Dr D. Schneider for a program for handling the D11 data. This work was supported by an EMBO travel grant (G.B.) and by grant 3.008.76 from the Swiss NSF (J.S.).

Proximity of two tryptophan residues in dihydrofolate reductase determined by ^{19}F NMR

NUCLEAR magnetic resonance methods have provided a wealth of information on the conformational and ligand-binding properties of proteins^{1–3}. In such studies, it is necessary to resolve resonances from the ligand or from individual residues of the protein. To achieve this, it is often necessary to resort to isotopic substitution methods such as selective deuteration^{4,5} or ^{13}C enrichment^{6–8}. An alternative approach is to introduce a fluorine atom (^{19}F) into the system as an NMR probe, either by using fluorine-containing ligands^{9–11} or by labelling the protein itself. This can be done either by chemical modification^{12–15} or by the biosynthetic incorporation of selected fluorinated amino acids^{16–19}. We have used this latter approach to prepare *Lactobacillus casei* dihydrofolate reductase containing either 3-fluorotyrosine or 6-fluorotryptophan residues; by measuring the ^{19}F spectra at 94.1 MHz we have characterised the effects of ligand binding on individual tyrosine and tryptophan residues in the protein¹⁹. We now report through-space ^{19}F – ^{19}F spin–spin coupling in 6-fluorotryptophan containing dihydrofolate reductase which demonstrates that two of the tryptophan residues are in close proximity in the folded structure of the protein.

Figure 1a shows the ^1H noise-decoupled ^{19}F NMR spectrum at 94.1 MHz of 6-fluorotryptophan-containing dihydrofolate reductase in its ternary complex with methotrexate and NADPH. Each of the five fluorotryptophan

Fig. 1 a, The proton noise-decoupled ^{19}F NMR spectrum at 94.1 MHz of a 1 mM solution of 6-fluorotryptophan-labelled dihydrofolate reductase in the presence of 1 equivalent of methotrexate and 1 equivalent of NADPH. The sample was examined as a D_2O solution containing 50 mM potassium phosphate, 500 mM potassium chloride, pH 6.5 (meter reading); sample temperature was 11 °C. Details of the purification of the enzyme and experimental conditions used for recording the spectrum are given in ref. 19. The high field signal has been assigned to two overlapped ^{19}F signals; however, more recent sequence studies (K. Batley and H. R. Morris, personal communication) suggest that the enzyme contains only four Trp residues. b, The proton noise-decoupled ^{19}F NMR spectrum of the same sample at 254 MHz (sample temperature 28 °C). The additional sharp signal at zero frequency arises from a small amount of denatured enzyme which appears on standing.

residues gives rise to a ^{19}F NMR signal. It can be seen that two of the signals appear as doublets, with components of approximately equal intensity and with splittings of equal magnitude (17 ± 2 Hz). Clearly, since all the ^1H nuclei are being irradiated, these splittings cannot arise from ^1H - ^{19}F spin-spin interactions. The two remaining possibilities are, first, that the splitting is a spin-spin coupling, which must be a ^{19}F - ^{19}F coupling since there are no other spin- $\frac{1}{2}$ nuclei present a 100% abundance in the system or, second, that the splitting is a chemical shift difference, reflecting the presence of two equally populated conformational states of the protein. These two possibilities can be distinguished either by spin-decoupling ($\{^{19}\text{F}\}-^{19}\text{F}$) or by studying the field-dependence of the splitting, since chemical shift differences are directly proportional to the strength of the applied magnetic field, while spin-spin couplings are field independent. We have now examined the ^{19}F spectra at 2.7 times higher field strength (254 MHz for ^{19}F) and find that the splittings are again 17 ± 2 Hz, that is they are independent of the operating frequency and thus correspond to spin-spin interactions and not to chemical shift differences. The constancy of the splittings can be clearly seen in Fig 1a and 1b where the spectra at 94.1 and 254 MHz are presented on the same frequency scale. Instrumental limitations have prevented us from carrying out the triple resonance experiment (^1H and ^{19}F irradiation) required to demonstrate ^{19}F - ^{19}F homodecoupling. However, we have been able to confirm that the doublets arise from homonuclear ^{19}F - ^{19}F spin-coupling by studying the ^{19}F spectra obtained using Carr-Purcell pulse sequences ($\pi/2-\tau-\pi-\tau$)²⁰. In these experiments the singlet echo resonances decayed as a function of $\exp(-2\tau/T_2)$ whereas the doublet echoes decayed as $\exp(-2\tau/T_2) \cos(2\pi J\tau)$ as would be expected for doublets arising from homonuclear spin coupling. When $2\tau=1/J$, inverted signals are observed for such a doublet while the singlets are not inverted. An analysis of the amplitude of the high field doublet signal (see Fig. 1) as a function of τ gives $T_2 = 38 \pm 8$ ms and $J_{\text{FF}} = 21 \pm 2$ Hz.

We therefore conclude that we are observing, for the first time, ^{19}F - ^{19}F spin-spin coupling between the nuclei on different tryptophan residues in the protein.

Such coupling is termed 'through-space' coupling, since there is no inductive mechanism available. The concept of through-space coupling is well-established in small molecules²¹⁻²⁶ where the interacting nuclei are close together in space though separated by four or five σ bonds. For such through-space coupling to occur the fluorine atoms must be sufficiently close together ($<4\text{\AA}$) for there to be significant orbital overlap²²⁻²⁶. As the internuclear separation decreases to 3Å coupling constants of approximately 20 Hz have been observed and further decrease in the internuclear distance leads to a sharp increase in the magnitude of the coupling constant. We conclude that two fluorotryptophan residues in *L. casei* dihydrofolate reductase must be so disposed that fluorine substituents are approximately 3Å apart (approaching van der Waals contact). Since no two tryptophan residues are adjacent in the primary structure of the protein (K. Batley and H. R. Morris, personal communication), this proximity must be a consequence of the folded structure of the protein. (It is apparent in Fig. 1b that the resonance of the denatured enzyme shows no splitting.) The measurement of through-space ^{19}F - ^{19}F spin coupling constants clearly provides us with a sensitive method of detecting conformational changes in this part of the protein. In a series of complexes with substrate, coenzyme or inhibitors (alone or in combination) the magnitude of the splitting was completely unchanged, even though the chemical shifts of these two ^{19}F signals changed by up to 1 p.p.m.¹⁹. Thus, although the environment of the two tryptophan residues changes, their relative position does not.

The observation of through-space ^{19}F - ^{19}F coupling in proteins opens up an entirely new source of information on protein structure and protein-ligand interactions in solution. A systematic study of a series of selectively fluorinated derivatives of a protein could provide much valuable information on the proximity of individual residues to one another in the protein. The principle of the method could readily be extended to studies of interactions between fluorine-containing ligands and fluorine-containing proteins. The appearance of through-space coupling between a nucleus on the ligand and one on the protein is entirely feasible, and would provide unique information on the structure of the binding site in solution. Through-space ^1H - ^{19}F coupling also occurs²⁶, and would open up further possibilities for the study of protein-ligand interactions using a fluorine-containing ligand and a normal protein. It should be noted that spin-coupling constants can be detected only in the spectra of low-molecular weight proteins: for higher molecular weight proteins ($>30,000$) the short relaxation times preclude such measurements.

The information obtained from observations of through-space coupling is similar to that which can sometimes be obtained from studies of the nuclear Overhauser effect^{27,28}, and a combination of the two approaches should provide structural information on proteins in solution. We plan to explore the potential of these methods fully in our studies of ^2H - and ^{19}F -labelled dihydrofolate reductase.

matters arising

Molecular chirality of life and intrinsic chirality of matter

BONNER *et al.*¹ stated that if racemic DL-leucine was bombarded with left-handed electrons (-1 helicity) plus their bremsstrahlung, the D enantiomer decomposed more quickly, whereas with right-handed electrons ($+1$ helicity) plus their bremsstrahlung the L enantiomer decomposed faster. In an aqueous system of D- and L-tyrosine and using only natural, left-handed β^- particles and their bremsstrahlung radiation I found² similar results in 1968. Bonner *et al.*¹ referring to my experiment, wrote: "One of us has been unable to repeat Garay's original type of experiment". They used the word 'repeat', erroneously. Bonner² certainly repeated parts of my experiment for his paper but he used only bremsstrahlung radiation and left out β^- particles from the reaction mixture. This altered the situation fundamentally and therefore it cannot be considered repetition. Bonner *et al.* discussing their results, state: "We do not know whether the asymmetric degradations are caused by the longitudinally polarised electrons or by their bremsstrahlung"¹. Thus the presence of longitudinally polarised electrons are clearly important. According to our hypothesis^{8,9} and to a similar one put forward by Noyes³, longitudinally polarised electrons are responsible for stereoselective degradation. Additionally, Keszthelyi^{4,5} and Walker⁶ pointed out that selective decomposition of enantiomers cannot be caused by bremsstrahlung. Finally, in recent experiments, Darge *et al.*⁷ studied the stereoselective decompositions in a similar system. They changed the radiation source and target molecule, but did not omit β^- particles from the reaction mixture. Referring to my work they wrote that their result "is in qualitative agreement with previously reported experiments on the interaction of D- and L-tyrosine with β^- particles".

BONNER, VAN DORT AND YEARIAN
REPLY—Garay quotes incompletely from our paper¹ on the asymmetric degradation of DL-leucine, then claims that we use the word "repeat" erroneously. We said¹, "In addition, one of us has been unable either to repeat Garay's original type of experiment with alkaline DL-tyrosine or to observe the induction of optical activity in a number of other racemic amino acid substrates as well". Neither in this quote nor in the paper to which it refers² do we claim an attempt to repeat Garay's exact experiment. In fact, we elaborate in detail on the reasons for which we modified Garay's experimental protocol, because² "we have felt some slight misgivings about Garay's experiment. In the first place the β -source was relatively weak, only about 0.36 mCi of $^{90}\text{SrCl}_2$. Second, the intended reaction was not primarily induced by the β -rays or their bremsstrahlung, but only presumed to be in some way enhanced by them. Thus the effect was noted only in alkaline, but not acidic solution. Third, the reaction was conducted in aqueous-ethanol solvent, where solvent photochemistry or radiochemistry (which would involve symmetrical radical intermediates) would be superimposed upon and might obscure any actual asymmetric β -ray or bremsstrahlung effects. Lastly, we felt that mere differences in the shapes of two ultraviolet absorption spectra were hardly the best or most convincing criteria for the generation of optical activity. For these reasons we decided to repeat Garay's type of experiments, with considerable modifications which would hopefully circumvent some of the above drawbacks." Since the Vester–Ulbricht β -decay mechanism³ which we were investigating involves β -ray bremsstrahlung, we used² the strongest bremsstrahlung source we could locate, 61.7 kCi of ^{90}Sr – ^{90}Y oxide in storage at Oak Ridge National Laboratory. To minimise other sources of ambiguity inherent in Garay's original experimental design we irradiated both racemic as well as optically-active amino acids, both crystalline and in solution, then analysed the percentage degradation and enantiomeric composition of the radiolysed samples by gas chromatography. Clearly, these experiments represented extensions of and not a repetition of Garay's original experiment. In none of these experiments was asymmetric degradation observed. Our subsequent suc-

cessful asymmetric degradations of DL-leucine with longitudinally-polarised linear accelerator electrons of both handedness¹ involved crystalline amino acid targets in a collodion matrix under high vacuum, and certainly also do not remotely approximate Garay's original experimental conditions. Nor do the recent experiments of Darge⁴ involving the radiolysis of DL-tryptophan by ^{32}P in a frozen ice matrix constitute a duplication of Garay's experiment. The simple fact is that no one, including Garay, has made an attempt to repeat his original experiment exactly, and no one has claimed to.

Do viruses use calcium ions to shut off host cell functions?

DURHAM¹ suggests that Kamine and I² have been "misled into putting false emphasis" on the role of Mg^{2+} relative to Ca^{2+} in controlling cellular metabolism because we have been unduly influenced by the fact "that cells respond more to changes in external Mg^{2+} than Ca^{2+} ". This represents a ordinate control of metabolism and misreading of my reasons for proposing a central role for Mg^{2+} in the co-growth of animal cells. These reasons were set out at greater length previously^{3,4} and have been reiterated and expanded more recently (see ref. 5 for example). My emphasis on a regulatory role of Mg^{2+} stemmed from the observations that any of a variety of unrelated substances which stimulate the multiplication of chicken embryo fibroblasts in culture, also stimulate a singular array of reactions associated with transport⁶, energy metabolism⁷, differentiated function and macromolecular synthesis^{8,9}. This singular array was termed the coordinate

response^{3,5} and includes reactions which are independent of one another and of macromolecular synthesis. Therefore, it was necessary to invoke an intermediary agent between external signal and intracellular response with the capacity to modulate many different metabolic pathways at the same time. The only specific enzymatic steps then known to be accelerated by the stimulatory treatments were the transphosphorylation reactions of glycolysis^{7,10}, all recognised as control points in this pathway and all requiring Mg^{2+} (refs 11–13). It has also become evident that some key regulatory enzymes vary in activity with their degree of phosphorylation^{14,15} and that the activities of the protein kinases or phosphatases which determine this degree are sharply dependent on $[Mg^{2+}]$ in the physiological range. In a slightly different cellular domain, we have shown that the rates of uptake of hexoses and uridine into chicken embryo cells, which are governed coordinately by external effectors, can be controlled by Mg^{2+} , but not by Ca^{2+} , in a manner that simulates in detail the kinetics of the physiological response¹².

It is generally agreed that over 90% of the Mg^{2+} in cells is bound, largely to membranes and macromolecules^{17–20}. Changes in configuration of the binding structures or in their microenvironment would alter the availability of Mg^{2+} for its metabolic tasks. Increasing the permeability of the cell membrane to Mg^{2+} would also tend to drive up the intracellular concentration of Mg^{2+} (ref. 21). Because the estimated concentration of free intracellular Mg^{2+} is less than that required for maximal activity of many key regulatory enzymes^{11–14} any small change would have far reaching effects²².

By contrast, the concentration of free Ca^{2+} in cells is far too low²³ to affect the regulatory enzymes of the pathways involved in the coordinate response^{3,5}. Perhaps some mechanical responses which involve proteins with a very high affinity for Ca^{2+} are under its control. But, the remarkable sequestering power of the cell for Ca^{2+} (ref. 24) would ensure that such a response would be short-lived, unlike the coordinate response which is maintained for many hours, requires continuing stimulation, and culminates in accelerated cell division.

There would seem to be some merit in Durham's suggestion that the inhibition of cell metabolism which accompanies infection by cytotoxic viruses is caused by a gross increase in intracellular Ca^{2+} following damage to the cell membrane. This follows from the observation that an internal Ca^{2+} level, $[Ca^{2+}] \geq 10^{-4} M$ interferes with key Mg^{2+} -dependent reactions in the cell^{25,26}. Beyond such pathological

effects, however, the role of Ca^{2+} seems likely to be restricted to short-term structural and mechanical responses in keeping with the pulse-like, localised nature of its fluctuations, and to the limited number of proteins which can respond to $[Ca^{2+}]$ within the physiological range of $<10^{-7}$ – $10^{-3} M$. Long-term inhibition of metabolism by Ca^{2+} deprivation may be the indirect result of lowering free Mg^{2+} within the cell⁴.

DURHAM REPLIES—The best current estimates of ion concentrations in resting eukaryotic cytoplasm are around $10^{-3} M$ for Mg^{2+} and $10^{-7} M$ for Ca^{2+} . This 10^4 -fold difference explains why Ca^{2+} and not Mg^{2+} is used as a short-term intracellular signal in movement, hormone action, synaptic transmission, protozoan chemotaxis, vision and bioluminescence. Powerful homeostatic mechanisms tend always to maintain very low cytoplasmic Ca^{2+} concentrations. Prolonged overwhelming of these mechanisms would produce a spectrum of changes strikingly like those produced by many lytic or transforming viruses.

Rubin and his colleagues have shown clearly that changes in extracellular Mg^{2+} concentrations can greatly affect cells. Others have shown analogous responses to extracellular K^+ or H^+ levels, and to agents that affect polyamine metabolism. Responses to extra-

cellular Ca^{2+} are notoriously variable, however, even for processes that undoubtedly involve intracellular Ca^{2+} . One reason is that eukaryotic cells conduct most Ca^{2+} fluxes across internal membranes, to and from substantial calcium reservoirs for which there are probably no magnesium equivalents. In the long term, feedback relationships between different ions tend to obscure the primary ion fluxes, so that one is probably wise not to make categorical statements about any one ion.

Rubin's statement that the cytoplasmic Ca^{2+} concentration is too low to affect the "coordinate response" is wrong. Micromolar Ca acts on adenyl and guanyl cyclases and phosphodiesterases, with consequent effects on cyclic nucleotide levels and kinase activities. It also acts on K^+ and other ion fluxes, and on DNA precursor synthesis. Rubin's implication that intracellular Ca^{2+} ions act via Mg^{2+} -dependent reactions can be only partly true.

Rubin and I agree that cell biologists frequently postulate, and then expensively seek, macromolecules to fill roles that ions can fill much more simply.

Cholinergic link in yawning

HOLMGREN *et al.*¹ recently focused attention on the basic mechanism behind the act of yawning. They reported that physostigmine and pilocarpine induce yawning in young male rats and hypothesised that a central cholinergic link may be involved in the reflex. Our results support such a proposal.

Yawning is a characteristic sign of withdrawal from morphine in man² and monkeys³. When naloxone (0.5 mg per kg body weight), but not physiological saline, was injected subcutaneously (s.c.) into three 'ex-addict' baboons (two male and one female, 4.4–5.2 kg), 98 d after abrupt withdrawal of morphine, a low incidence of yawning (2–4 episodes) occurred within 15 min; on this occasion, other signs of long-term withdrawal were absent. Seven days later, the same baboons were again challenged with naloxone. 20 min after physostigmine (0.05 mg per kg s.c.). Although this dose of physostigmine *per se* did not elicit yawning, with each animal there was a threefold increase in the incidence of yawning.

Although a cholinergic link may indeed be involved in yawning, it should be recognised that other factors are also important. Thus, dimethyltryptamine causes

yawning after intramuscular administration to rhesus monkeys⁴ yet there is no evidence that this hallucinogen has marked effects on the cholinergic system in this species.

A. COWAN

4. Brewster, J. M., Siegel, R. K., Johnson, C. A. & Jarvik, M. *Int. Pharmacopsychiat.* 11, 102–108 (1976).

URBÁ-HOLMGREN AND HOLMGREN
REPLY—In Cowan's experiments with 'ex-morphine addict' baboons, although physostigmine 0.05 mg per kg s.c. *per se* did not evoke yawning, this dose strongly potentiated naloxone-induced yawning. Perhaps a higher dose of physostigmine (0.10 mg per kg) would have elicited yawning directly even in monkeys, as it does in rats¹ and in infant guinea pigs, kittens and dog pups (unpublished observations). In infant rabbits we have had to use a still higher dose (0.15–0.20 mg per kg).

We certainly agree with Cowan that other factors are also important in yawning. The stretching and yawning syndrome induced by ACTH and MSH (quoted in ref. 1) is a well-known example. In recent experiments with (3,4 dihydroxyphenylamino)-2-imidazoline (DPI, Böhringer) we have observed that this drug, which according to Cools *et al.*² has a specific and potent agonistic activity at dopamine inhibitory receptors, in doses of 5 mg per kg intraperitoneally, elicits moderate, but statistically significant yawning in infant rats (from 9 to 15 d in age). It would be rash at this stage, to hypothesise that drugs shown to elicit the yawning act necessarily through a final common path including a cholinergic link.

Lysogeny by f2 phage?

ZGAGA¹ claims to have produced "the first demonstration that bacteria can also contain the genetic information for the production of an RNA phage", and raises the question whether RNA phages can lysogenise their host in certain conditions. Her criteria are the "spontaneous release of

phage particles" and the "immunity" of the host to superinfection.

Davern², and Hoffmann-Berling and Mazé³ reported that *Escherichia coli* infected with RNA phage (can₁ or fr, respectively) when incubated at 32°C rather than 37°C seemed to grow normally while producing phage at a low level. The suggestion that single infected cells excreted phage without lysing³ has been challenged⁴. Davern further noted that even at 37°C phage-infected cultures showed variable degrees of lysis and the surviving cells seemed to multiply normally while producing phage indefinitely in successive cycles of subculture. Such cells, when used as host bacteria in a plating assay, did not permit formation of plaques. The latter observations have been repeated several times in our laboratory when indicator bacteria have been accidentally contaminated with phage.

The state in which bacterial cultures produce phage without lysing and are resistant to superinfection has been called 'carrier state'² or 'viral persistence'⁵ without implying any mechanism. Resistance to lysis occurs in certain physiological states of *E. coli*⁶ and resistance to superinfection (interference) has been described as a normal consequence of RNA phage infection⁷. The phenomena described by Zgaga are reminiscent of the earlier observations and raise the question whether guanidine is required to establish cultures of bacteria "containing genetic information for f2 biosynthesis".

The term 'lysogeny' implies that the viral genome is present in the host in a non-infectious form, in particular that it is integrated into the host genome⁸; until evidence for such criteria is adduced in the case of RNA phages it would be preferable to retain the original designation of 'carrier state'.

ZGAGA REPLIES—Weissmann's objection is based on the observations of Davern¹ and of Hoffmann-Berling and Mazé², that *E. coli* infected with some RNA phages apparently grow normally at lower temperatures while producing phage at a low level. Loeb and Zinder³ showed that at 37°C f2 phage lyse the bacteria they infect. Lerner and Zinder⁴ showed, by the study of release of bacteriophage f2 from single infected cells, that at 30°C as well as at 37°C phage are released by cell lysis,

and not by excretion from intact cells. Therefore, the definition of 'carrier state' mentioned by Weissmann ("the state in which bacterial cultures produce phage without lysing and are resistant to superinfection") obviously cannot be attributed to phage f2.

Originally, 'carrier state'⁵ denotes "bacterial cultures that are persistently contaminated with phage, but from which uninfected cells could be recovered readily". Thus, the maintenance of this state depends on the presence of free phage and sensitive bacteria. To eliminate any possibility of reinfection during bacterial growth, female (*con. f2*) cells, which are genotypically resistant to f2 phage, were constructed. It turned out that F[–] (*con. f2*) bacteria produce phage spontaneously. In addition, 'carrier state' is not stable. Therefore phage-free, sensitive clones can usually be isolated by growth in the presence of phage antiserum, or by serial subcultures of single colonies⁶. On the contrary, the principal feature of 'lysogeny' is its stability. Hayes said⁷: "In practice, the existence of lysogeny should be judged by rather rigorous criteria of its stability, since interaction of some virulent phage with their hosts may superficially simulate the condition" ('carrier state'). (*Con. f2*) state, once established, has been stable for 2 yr. It is stable in male as well as in female cells and quite unaffected by serial subculture of single colonies or by antiserum treatment.

The functional state and the location of genetic information for phage production in (*con. f2*) bacteria are still under investigation. But, I do not agree with Weissmann's notion that the term 'lysogeny' in particular implies, that the viral genome is integrated into the host genome. For example, in lysogens carrying phage P1, the prophage does not occupy a characteristic site, if any, in the bacterial chromosome⁷, but there is strong evidence to suggest that it is a nonchromosomal element⁸, and a part of the bacterial membrane replicatory system^{9–11}.

reviews

Astronomy of Stonehenge

Jack Meadows

On Stonehenge. By Fred Hoyle. Pp. v+128. (Heinemann Educational: London, 1977.) £4.50.

SOME time ago, I acted as External Examiner at another university, and wanted to interview one of the candidates. She was nowhere to be found. Further enquiries elicited that she had recently become a devotee of Stonehenge; and I had been foolish enough to select the summer solstice for my oral examinations. She had chosen to attend the more important event on Salisbury Plain. I wondered then, not for the first time, what it is about Stonehenge that sets it apart in people's minds from other megalithic monuments. This even extends to discussions of its possible astronomical significance. After all, Thom has suggested that a number of the standing stones up and down the country indicate an astronomical orientation, so why do at least half of all relevant writings concentrate on Stonehenge?

Respectable reasons can certainly be advanced—the impressive size of the monument, the constructional capabilities that must have gone into its creation, the choice of site, the span of time over which it was used and modified. I suspect, however, that part of the cause of Stonehenge's attraction, even for reputable investigators, remains its extra-scientific glamour. Typically, Sir Fred Hoyle has his own different reason for studying Stonehenge:

"Because of my interest in Stonehenge, I am often asked to comment on other ancient monuments—Avebury, the Egyptian pyramids, Mayan temples, and so forth. It usually causes surprise when I express no interest. My indifference comes from a lack of definition of the problem. Given the plan of Avebury, it would be possible to invent many hypotheses about the purpose of this monument, so many indeed that soon or later, just at random, the investigator would come on something which seemed to have a tolerable correspondence with the facts. For me, the case of Stonehenge was quite different. Thanks to the work of Mr Newham and Professor Hawkins, the problem here is defined, particularly if we go on to add, as Professor Hawkins also did, the further assertion that the purpose of Stonehenge was to predict eclipses of the Sun and Moon. The problem is then defined with severe constraints. Without modifying the fixed structure in any

way, can Stonehenge be used in a literal, practical way to predict eclipses successfully? Since the successful prediction of eclipses is a complex problem, an affirmative answer to this question would certainly not be expected unless eclipse prediction was indeed the purpose of Stonehenge. The question is so definitive, permitting no room for manoeuvre, that its investigation is quite explicit."

There speaks the Cambridge-trained theoretician: we know precisely where we are (even if it is a little harsh to imply that no other site has yet had its problems properly defined).

Hoyle's book therefore has a single, limited purpose—to examine the possibility that Stonehenge was used as an eclipse predictor—and the author deploys his considerable skill as a writer in presenting his arguments and conclusions clearly and concisely. The main body of the text, though closely argued, uses no mathematics, and should be comprehensible to a wide range of readers. (The diagrams, incidentally, are genuinely helpful.) An appendix re-defines the problem in terms of spherical trigonometry; and also brings us face to face with one of the main queries concerning astronomical orientations—namely, their statistical significance. Two types of question come under this heading. The first is this: since alignments are never perfect—due, for example, to subsequent movement of the stones and to their finite breadth—what latitude of error can be permitted when deciding whether two objects are aligned towards a particular point on the horizon? Again, if a large number of possible alignments can be found (as they can at Stonehenge), what is the likelihood that astronomically significant ones will occur by chance? Hoyle examines both these points with care. He concludes with regard to the second, that the probability of chance alignments is higher than Hawkins supposed in *Stonehenge Decoded*, but is still too small to explain all the observed alignments at Stonehenge.

The discussion of Stonehenge's use as a predictor of solar and lunar eclipses essentially follows lines that Hoyle has put forward previously, though laid out here in greater detail. In particular, he spends some time considering the vexed question of how exactly observations of objects on the

horizon might have been made. This is linked to the discussion of alignment errors; since both the Sun and the Moon show a finite disc. His argument here is ingenious. He suggests that some of the apparent spread in alignments at Stonehenge, as compared with the expected directions, is due to the method of observation that was used. As a result, evidence previously used to cast doubt on an astronomical interpretation of Stonehenge, may actually support it. It is only fair to add that some of the details of the observational procedure he outlines may be open to question. The general picture, however, hangs together very well, and leads on to an interesting speculation regarding the successive stages of construction at Stonehenge.

One of the problems in interpreting Stonehenge as an astronomical observatory is that the first structure built (Stonehenge I) seems to indicate a more sophisticated approach than the final stage (Stonehenge III). This obviously runs counter to common-sense expectations. Hoyle suggests that, in the period between the two phases of building, the method of eclipse prediction changed. Stonehenge III has an inner horseshoe of 19 bluestones, and he relates this to the Saros—the 19-yr cycle that was used in antiquity to predict eclipses. Recognition of the Saros, however, almost certainly required access to written records; whereas the analysis behind Stonehenge I could have been carried out on the basis of a simple counting system. On this interpretation, Stonehenge III does not reflect a simpler understanding of eclipses than Stonehenge I: rather, the complexity has been removed from the structure and stored in another form. A numerate culture became a literate culture.

The way we interpret Stonehenge necessarily affects what we think of the people who built it. Archaeologists currently seem somewhat less concerned about the level of abstract thought implied by a Stonehenge astronomical observatory than they were a decade ago. Nevertheless, the cultural implications continue to be controversial. In the final chapter of the book, Hoyle adds his own mite to this debate. He suggests that the (invisible) nodes of the lunar orbit, which he believes

were tracked by way of the Aubrey holes at Stonehenge, might have come to be worshipped as a powerful, though unseen, god. He therefore concludes the book by querying: "Could a distant memory of [the Sun, Moon and lunar nodes] be the origin of the doctrine of the Trinity, the 'three in one, the one in three'? I suspect so. In Stonehenge I may well be many roots of our present-day culture."

No doubt the student who stood me up for Stonehenge will feel confirmed in her choice by these words. Those who would not wish to venture so far should, nevertheless, be grateful to Sir Fred Hoyle for setting out the case for an astronomical interpretation of Stonehenge in such a readable manner.

Jack Meadows is Professor of Astronomy and History of Science at the University of Leicester, UK.

Microscopic techniques

Analytical and Quantitative Methods in Microscopy. Edited by G. A. Meek and H. Y. Elder. Pp. 276. (Cambridge University: Cambridge, London and New York, 1977.) Hardback £12; paperback £4.75.

THIS volume originates in a symposium on principles, applications and shortcomings of some techniques in modern microscopy, organised under the auspices of the Society for Experimental Biology in 1975. It consists of an introduction and twelve chapters. The topics considered are stereology, optical diffraction analysis, quantitative fluorescence microscopy, image analysis, integrating microdensitometry, scanning microinterferometry, STEM, microanalysis of various sorts, and cryoultramicrotomy.

Most of the chapters are written in a clear instructive style which is fairly easy to follow, although some of the authors have lapsed on occasion into the more easily produced review type of text. The editors have done well to cajole a panel of authors of this size into producing a reasonably uniform style and standard of presentation. The chapters seem to have very few statements to which one could take specific objection, although it is difficult for one person to critically encompass accounts of all of these topics. Each of the chapters is at such a level and of

a style as to make it very suitable first reading for a research student or a more senior researcher contemplating working in one of these areas of technique. Such readers will get a helpful mechanistic accounts of the methods concerned. The chapters by R. W. Horne (optical diffraction analysis), D. J. Goldstein (microinterferometry and microdensitometry) and S. Bradbury (quantitative image analysis) are particularly helpful and timely accounts.

Perhaps it should be asked how fair a picture this book gives of microscopy today. Taken together, they describe methodology that finds use at present in a small minority of research projects. The overall picture of microscopy presented in this volume is one that emphasises certain (sometimes quite isolated) specialities. It is for the most part about the iced cakes of microscopy rather than the bread and butter.

Perhaps the ultimate test of a book that is designed for the teaching of a technique is to see if it can tell the researcher whether a particular approach is appropriate for answering the questions he wishes to ask. I am not certain how many of the chapters pass this test, but there are some really excellent helpful accounts of certain microscope technologies in this book. The paperback version, in particular, is fine value.

M. A. Williams

M. A. Williams is Reader in Human Biology and Anatomy at the University of Sheffield, UK.

Insect behaviour-modifying chemicals

Chemical Control of Insect Behaviour. Edited by H. H. Shorey and J. J. McKelvey, Jr. Pp. 414. (Wiley-Interscience: New York and London, 1977.) \$24.50; £14.65.

THIS book is the eighteenth publication in the series *Environmental Science and Technology*, and deals with a subject that, because of its likely contribution to a more rational use of insecticides, is of particular

relevance to the study of the environment and the technology of its conservation. All types of behaviour-modifying chemical known to influence insect behaviour by external reception, including pheromones and plant-derived compounds, are covered and their prospects in pest management are discussed.

Publication of the book has arisen from a conference, involving many leading workers in the field, held in May 1975 at Bellagio, Italy, with participants contributing authoritative chapters on the various aspects of the subject. After a short introduction, subsequent chapters are arranged into five sections. The first deals with the nature of sensory responses to

behaviour-modifying chemicals with many examples from electrophysiological studies. The next two sections are devoted to behavioural aspects and begin with a detailed account of the various mechanisms by which insects respond to distant odour sources. The fourth section considers the role of diversity in behaviour-modifying chemicals, with the approaches to their use in insect pest management reviewed at length in the final section. Each chapter has an extensive list of references including many publications from 1975. The book has a comprehensive subject index.

The present high level of research activity in chemical control of insect behaviour may mean that this book, dealing with the subject in such depth, will soon become out of date. Already, for example, the treatment of chemokinesis in chapter 5 has been revised by the author, and in chapter 9 a point is made based on a recently questioned report that the sex pheromone of *Musca domestica* consists of one compound. Nevertheless, since the authors have, with only a few notable exceptions, been cautious in drawing conclusions from the data presented and are mostly in a position to judge this data critically, the likelihood of serious reappraisal of much of the content is greatly reduced.

As the book is compiled from many individual contributions, apparently without too rigorous editing, there is inevitably some duplication of information, and in some cases the treatment of such data seems to be inconsistent. This often presents the reader, however, with the opportunity to compare the various current approaches to controversial issues. For example, the subject of kairomones is treated in several different ways, and a number of authors make different suggestions for improving definitions of the terms that have been devised to fulfil the requirements of the subject.

The prospects for insect behaviour-modifying chemicals in pest management are considered critically and without the rash claims typical of many earlier writings. In addition, a number of realistic suggestions for new approaches are made although it is asserted that more rapid progress would be made in pest management if priority could be given to fundamental research in certain listed areas.

There is no doubt that this book is to be recommended. It will be of most value to those already having some knowledge of the subject and will provide a stimulating background on which to base new research. In addition, those engaged in deciding priorities for future crop protection research and development will find this book a source of useful information and ideas.

J. A. Pickett

J. A. Pickett is Principal Scientific Officer co-ordinating chemical aspects of work on behaviour-controlling chemicals at Rothamsted Experimental Station, Harpenden, UK.

applied excellence

Advanced techniques in routine use at The Radiochemical Centre

Described below are just two examples of the many up-to-date techniques, which have been pioneered or applied for routine use at The Radiochemical Centre. These developments are part of our constant endeavour to maintain our position at the forefront of the specialised field of tracer methodology, so that we can continue our supply of radiochemicals of the highest quality and technical specifications.

Distribution of labelling in tritium compounds

Modern techniques for the production of tritiated compounds are more sophisticated than those used in the early days of tritium labelling, and produce compounds labelled in specific positions rather than generally labelled. Nevertheless, it is necessary for many tracer applications of tritium compounds to know the *precise* position and configuration of the tritium labels. Traditional chemical methods of doing this are tedious and time consuming and subject to considerable error, and so the routine supply of such information has until recently not been possible.

The Radiochemical Centre, in collaboration with the University of Surrey, has developed over the past eight years the technique of tritium nuclear magnetic resonance (tnmr) spectroscopy for this purpose. This method is much quicker and more accurate than the traditional chemical or biochemical methods for determining distribution of tritium labelling.

It is now used routinely to establish the distribution of tritium labelling produced by the usual methods of tritiation employed at The Radiochemical Centre. We supply accurate details as to the position and configuration of the tritium labels for an increasing number of our labelled compounds.

A number of examples are given below:

	[18, 20(n)-³H]TESTOSTERONE Code TRK.162 1α 5.9% 2α 8.2% 1β 46.0% 2β 39.9%
	[6-³H]BENZO[a]PYRENE Code TRK.501 6 >95% 1 <5%
	D-[2-³H]GLUCOSE Code TRK.361 2(α) 40% 2(β) 60%
	[G-³H]VINBLASTINE Code TRK.507 17 44% 11' 8% 12, 13 46% 14' 2%
	L-[3, 4(n)-³H]VALINE Code TRA/K.533 2 8% 4 64% 3 28%

The latest of our publications is as follows:

 CHAMBERS, V.E.M., CHAMBERS, V.M.A. and EVANS, E.A.,
Steroids vol. 28 (3), p.p. 359-375, 1976.

High performance liquid chromatography (HPLC)

This relatively new development of column chromatography is carried out using high efficiency microparticulate column packings of closely defined size.

Chromatography is carried out under pressure to ensure good flow rates and reduce diffusion of separated compounds. Dead volumes are kept to an absolute minimum. The result is that many separations can be carried out more quickly and with better resolution than with previously used chromatographic methods such as thin-layer chromatography or conventional column chromatography.

Work aimed at developing the applications of this method to radiolabelled compound separations is still in progress, but The Radiochemical Centre is already using the technique in many of its production processes, and in analytical applications. The result is purer compounds for the customer and greater efficiency of working.

The example illustrated below illustrates the clear superiority of HPLC when used as an analytical tool. The mixture used comprised the tritium labelled mono-, di- and triphosphates of adenosine, cytidine, guanosine and uridine, and all are clearly separated in the HPLC system.

Chemically transmitting synapses

Synapses. Edited by Glen A. Cottrell and Peter N. R. Usherwood. Pp. xviii+385. (Blackie: Glasgow, 1977.) £13.95.

THERE is a neatness and economy about the structure and function of chemically transmitting synapses that has given them an unfailing appeal for experimenters. The action potential, a brief all-or-nothing event, invades the presynaptic nerve terminal; the transmitter, synthesised and packaged on the spot, is released in quantal, countable packets; it combines with specific post-synaptic receptor sites which (in some situations at least) act to open or close discrete ionic channels in the membrane; the transmitter is then either metabolised on the spot by an enzyme appropriately lodged in the synaptic cleft, or it is taken back up by the presynaptic nerve for re-use. The whole thing seems to have an almost Toy-town quality.

To the extent that good science consists in reducing the confusion of a

half-understood mechanism to a series of discrete steps, this quality of our present understanding of synaptic function is a testimony to the excellence of past work in this field, and the casual observer might think that there was little left to be discovered. He would be wrong, of course, and this book, which is made up of a series of papers presented at a symposium in March 1976, highlights very usefully just those areas where mysteries still abound; in doing so, it obviously has to take for granted a great deal, and should be read as an introduction to the growing points and vague edges of the subject rather than as a coherent résumé of the present state of knowledge.

Among many interesting papers is a series of contributions about the vesicle hypothesis, written mainly by sceptics, and these constitute a very valuable source of information for students of this tangled controversy. It is a pity, perhaps, that papers by some of the ardent defenders of the vesicle hypothesis, such as Whittaker or Heuser, were not included.

Another fascinating theme that runs through several excellent papers in this volume is that of the formation and stabilisation of synapses, which is approached through studies on the synthesis and degradation of receptors (an

elegant contribution by Fambrough and his colleagues), the regeneration of synaptic connections after sectioning nerve bundles in the leech nervous system (Nicholls *et al.*), and studies on muscle denervation (Guttmann). This is surely one of the most challenging problems in neurobiology, and when we consider how badly understood is the mechanism even of the much-studied effect of denervation on the distribution of receptors in skeletal muscle fibres, it is obvious that the exploration has barely begun. The Toy-town image of the finished article seems a long way away when one is faced with the problem of how the synapse develops and regenerates.

Inevitably, in a published symposium, there are inconsistencies of style and quality. Overall, though, a very high standard is achieved, and the editors are to be commended for their choice of authors. Whether much purpose is served by including 40 pages of brief abstracts as an appendix to the main part of the book is doubtful, but this is a small criticism of an otherwise excellent book.

H. P. Rang

H. P. Rang is Professor of Pharmacology at St George's Hospital Medical School, London, UK.

Laboratory handbook on lysosomes

Lysosomes: A Laboratory Handbook. Second edition. Edited by J. T. Dingle. Pp. xiv+323 (North-Holland: Amsterdam, New York, and Oxford, 1977.) Dfl.136.00; \$55.50.

OF all the articles in the multi-volume *Lysosomes in Biology and Pathology*, edited by Dingle and his colleagues, those on techniques have been most frequently consulted. Dingle therefore decided to edit a laboratory handbook on lysosomes, which has proved sufficiently popular to justify a second edition.

The most useful chapter is a scholarly account of the properties of lysosomal enzymes by A. J. Barrett and M. F. Heath. This has been brought up to date with methods of assay and much background information. The chapter on isolation of lysosomes (R. T. Dean) follows for the most part traditional lines, using loading of rat liver with Triton, dextran, iron or gold. Methods for isolation of lysosomes from single cell types, such as leucocytes and tumour cells, are also given.

L. B. Bitensky and J. Chayen describe the histochemical identification of lysosomes at the light microscopical level, and rely on microdensitometry for quantitative results. The identification of lysosomes at the electron microscopical level is discussed by J. M. P. Schellens and his colleagues. Attractive results are obtained in various cell types by techniques for carbohydrates such as silver proteinate. Even reactions for enzymes such as acid phosphatase or β -glucuronidase can be misleading. Observations must therefore be approached with caution.

During the past five years, specific antibodies to individual lysosomal enzymes have been studied by A. R. Poole and others to monitor purity of isolated enzymes, inhibit their activity in cells and tissues and localise individual enzymes within cells.

In general, this is a fairly comprehensive account of recent techniques for lysosomes and their constituents, well illustrated and produced. It will be as welcome and widely used as the first edition.

Applications of geomorphology

Applied Geomorphology: A Perspective of the Contribution of Geomorphology to Interdisciplinary Studies and Environmental Management. Edited by John R. Hails. Pp. xv+418. (North-Holland: New York, Amsterdam and Oxford, 1977.) \$39.95; Dfl.98.00.

THE descriptive models of landscape evolution written in the sonorous prose of the last century were debated but only a little refined over 50 years, with too little attention being paid (though there were exceptions) to the mechanics of the processes invoked in sculpting type forms of the land surface. In comparatively recent years, enormous strides forward have been made, largely by application of quantitative methods in the laboratory and in the field. The subject is becoming established as a science in its own right, and though still interdisciplinary between civil engineering, geology and geography, the applied aspects compel its inclusion in optimisation of land use, in building science, and in pedology.

The subtitle of the book truly indicates the contents, written by nine authors, each an acknowledged leader in his field and (as in the editor's introduction) able to "communicate ideas comprehensible to others who have no geomorphological knowledge".

Some authors discuss widely, as in the chapter on weathering, with applications ranging from ore deposits to geomedicine, whereas others present thorough yet succinct summaries of their discipline; a very creditable example of this is the chapter on "Periglacial Environments". The chapter on irrigation and ground-water studies demonstrates how the success of irrigation schemes would be enhanced if designed to fit the geomorphic units compiled from interpretation of the geomorphic history of the area. Processes controlled by climatic differences have less importance in Karst hydrology, as the author of that chapter makes quite clear; he also cites Sweeting's view that the study of the development of Karst landforms has probably been hindered less by the dominance of cyclic ideas than by the lack of contact of workers in the different Karst regions. From work initially conceived in a spirit of academic enquiry, there is now much of importance to the engineer involved in dam building or using limestone aquifers as reservoirs or quarries for waste disposal.

The chapter on fluvial hydrology explains the relation between some of the many variables to be measured in

comprehending the river as an integration of the catchment morphology. Man's use and modification of rivers has often proved needlessly expensive in corrective measures applied where these measures opposed the natural forces.

The same can be said of the problem of routing motorways, with examples in the chapter on soil mechanics of slopes. The degree of stability of previously stable slopes cannot yet be predicted.

It seems paradoxical in the chapter on deserts to see the stress on removal of sediments by water: though widely spaced in time, these processes are critical in terrain classification and environment.

For resource appraisal, trafficability and management problems, systems of terrain classification, with subgroups of land units, are explained using block diagrams, maps and tables to help comparison of different methods and applications.

A chapter on coastal zone planning and management includes sea defences,

off-shore banks and beach stability, and discusses how these can be affected by tourist use, by mining and by construction works.

Inevitably, the great range of style and subject matter compels dipping into the book for a synopsis of specific aspects; but the 20 pages of index are inadequate for the reader looking for specific topics across different chapters—for example, rates of rock wear or removal by different geomorphic processes. The 35 pages of references are very valuable and would have been doubly so if the page number could have been added to indicate where referred to in the text.

There are numerous maps, tables and graphs and nine half-tone plates, leavening a most valuable summary of some quite difficult branches of this global science.

H. Lister

H. Lister is Reader in Physical Geography at the University of Newcastle upon Tyne, UK.

Differentiation in cellular slime moulds

Development and Differentiation in the Cellular Slime Moulds. Edited by P. Cappuccinelli and J. M. Ashworth. Pp. xx+317. (Elsevier/North Holland: Oxford, New York and Holland, 1977.) Dfl. 79; \$39.75.

THIS volume is a collection of papers from an EMBO workshop held in April 1977. One is grateful that it has been published so quickly, but this advantage is somewhat diluted by the way in which the book is printed. The typewritten manuscripts have been directly photocopied and greatly reduced; as a result some of the papers are either so faint or the print so small that they require hard work to read. What with the high price of the volume, the least the publishers could have done is to issue a magnifying glass with each copy, like the compact edition of the Oxford English Dictionary.

Cellular slime moulds are having a burst of popularity, and this excellent collection of papers gives one a good view of current progress. Many of the papers are mixtures of reviews and new results, some of the latter being significant advances.

To show where the main interests lie at the moment, I have made a list of the areas covered in the symposium: six of the papers are on some aspect of differentiation; five on cyclic AMP pulsations and their various effects in-

cluding their role in chemotaxis; four studies which in some way relate to problems of transcriptional and translational control of protein synthesis; three on different aspects of genetics; two on the plasma membrane; and one each on cell contact, cell division, polyamines, and modelling biochemical pathways.

One theme that runs through a number of papers is the rôle of cell contact on different aspects of development. J. Gross *et al.* found that cell attachment during aggregation, the rate of cyclic AMP signalling and the appearance or disappearance of certain proteins, all change at the same time. H. V. Rickenberg *et al.* show that cell contact is not necessary for the synthesis of alkaline phosphatase in cells grown in liquid culture if the suspension of separate cells is pulsed with cyclic AMP. H. F. Lodish and T. H. Alton provide evidence suggesting that at early stages when cells are separate, protein synthesis is controlled at translation, since there are numerous mRNAs present which are not translated. At aggregation, however, transcriptional control takes over and all the mRNAs are directly used to make new protein.

It is fitting that this interesting collection of papers should be dedicated to Kenneth Raper who discovered *Dictyostelium discoideum* and led the way in showing the exceptional usefulness of cellular slime moulds as experimental organisms.

J. T. Bonner

J. T. Bonner is Professor of Biology at Princeton University, New Jersey.

obituary

J. E. Littlewood

PROFESSOR John Edensor Littlewood, FRS, Emeritus Rouse Ball Professor of Mathematics in the University of Cambridge, died on 6 September, 1977, at the age of 92.

He was the son of Edward Thornton Littlewood, a schoolmaster who had been 9th Wrangler in 1882. Littlewood was taught mathematics at St. Paul's School by F. S. Macaulay, later FRS, an outstandingly successful teacher. Littlewood has described his mathematical education, including his early experiences in research, in *A Mathematician's Miscellany*, and it seems to have been a far from ideal preparation for the kind of research which became his life. For Cambridge mathematicians had not yet fully appreciated the major advances on the Continent.

His director of studies, E. W. Barnes, suggested the problem of integral functions of zero order, in particular asymptotic formulae for functions with given zeros. Perhaps as a result of independent reading, Littlewood switched to 'elementary' methods for general functions and produced an important result in his first paper on the maximum and minimum moduli of any integral function of zero order, a type of result which Barnes had described in 1898 as 'a disguised truism'. However, Barnes now recognised the value of the work; one referee opposed publication violently, but G. H. Hardy reported favourably and the paper was published in 1907.

In 1911, Littlewood opened a new chapter in the theory of series with his Abel-Tauber theorem which led to his immensely important collaboration with Hardy lasting 35 years.

It covered, besides the theory of series, and in particular Fourier series, the Riemann zeta function, Diophantine approximation, the additive theory of numbers and the theory of functions.

After three years in Manchester, Littlewood returned in 1910 to a Fellowship and Lectureship at Trinity College; he became Rouse Ball Professor in 1928. During the First World War he worked as a Second Lieutenant on anti-aircraft ballistics. He retained his rooms in Trinity as Life Fellow until his death. He spent little of any vacation in Trinity, finding a different setting better for concentration on research. He believed that periods of complete relaxation were essential and often found them in music, and in rock-climbing and skiing.

In his younger days he served on the Councils of his College, the Royal Society and the London Mathematical Society, but from about 1935 the fits of depression which had plagued him for many years seem to have become worse. He took no part in meetings of committees or councils or in gatherings of mathematicians. However, his fits of depression were cured sometime in the 1950s, and he paid several highly successful visits to the U.S.A. after retiring.

A very high proportion of Littlewood's work after 1912 was done in collaboration with Hardy, some with Paley, Offord, myself and others. When Harald Bohr, brother of Niels Bohr, paid his first long visit to Cambridge, he and Littlewood wrote a monograph on the zeta function, but, when it was finished, they were so exhausted that they could not take it to the printers. The manuscript was used later by Titchmarsh and Ingham

in writing their Tracts on the subject. Of the papers appearing under Littlewood's name alone, the one in 1925 made a very important contribution to the problem of the coefficients of functions *schlicht* in the unit circle, a problem still not completely solved.

Although in the early days there must have been many discussions with Hardy, most of their joint work was done by correspondence. It seems that there was an unwritten agreement that Hardy could write up and publish anything based on joint work, but Littlewood only allowed me to write up parts of our joint work on condition that it appeared under my name alone as 'based on joint work.' My own collaboration with Littlewood arose out of a D.S.I.R. memorandum on the nonlinear differential equations arising in radio work, and the most important result arose out of a letter to *Nature* 120 (1927), 363, by van der Mark and van der Pol on frequency demultiplication, or rather van der Pol's interpretation of it in *Proc. Inst. Radio Engrs* 22 (1934), 1051-1086.

I used to go to Littlewood's lectures on the theory of functions; some of them are included in his book of that title, and at one time he used the galley proofs. Although he had given the same lecture two or three times before, he showed such a passionate interest, always seeing things from a slightly different angle, that his audience could not help sharing his enthusiasm.

Littlewood's display of unequalled insight, technique and power as an analyst, was recognised by honorary doctorates, medals and membership of leading foreign academies.

Mary L. Cartwright

W. H. Sheldon

DR WILLIAM H. SHELDON, Director of the Biological Humanities Center in Cambridge, Massachusetts, died there on 16 September 1977. Sheldon is the man who invented somatotyping—a classification of variations in human body structure, to which he related variations in temperament, in physical and mental illness, and in patterns of growth and aging.

Born in 1898 in Warwick, Rhode Island, Sheldon grew up amid woods and marshes. His work shows the imprint of his country background; of his mother who raised five children and

was midwife to a village; of his father, a naturalist, breeder and judge of animals; and of his godfather William James, the psychologist and philosopher. At age 10 he was working for the state ornithologist, reporting on animals of the woods and fields—observing, describing, classifying. At 15 he took pride in his ability to match judges' scorings of livestock on 100-point scales. As an adult he turned his naturalist's eye on human structure and behaviour.

After public school, Sheldon attended Brown University and the University of Colorado. From the University of

Chicago he received his Ph.D. in psychology in 1926, his M.D. in 1933. He taught at Northwestern University and the Universities of Chicago and Wisconsin. A two-year fellowship in Europe allowed him to study with Jung and to visit Freud and Kretschmer.

In 1938 he moved to Harvard, where he did much of his basic research, with such colleagues as S. S. Stevens, the experimental psychologist, and E. A. Hooton, the physical anthropologist. During World War II he served as lieutenant colonel in the Army Medical Corps. From 1947 until 1959 he was Director of the Constitution Labora-

tory at the College of Physicians and Surgeons, Columbia University, succeeding Dr G. Draper, a pioneer in constitutional medicine. He has also held research appointments at the University of California, Berkeley, and, since 1951, at the University of Oregon Medical School.

Sheldon's earliest book (*Psychology and the Promethean Will*, 1936) and his latest one (*Prometheus Revisited*, 1975) are broad, provocative and provoking schemes for merging religious humanism with biologically grounded social psychiatry. Between these publications, he worked singlemindedly to propose and refine methods for describing individual human physical structure: to develop a "biological identification tag". Best known are his primary components of endomorphy (roughly speaking, the softness and roundness of a physique), mesomorphy (heaviness of bone and muscle development), and ectomorphy (attenuation, "stretched-outness"). By measuring the strength of each component in each individual and assigning a three-part index, the somatotype, Sheldon produced a tool which comes much closer to describing and encoding the great range of varia-

tions on the basic human body plan than was possible with older, pigeon-holing typologies.

Over the years his methods moved through several revisions, toward objectivity and always seeking measures that maximise invariance, that evaluate physique not just as a current manifestation but as a lifelong trajectory. Along the way he has reported associations of somatotype with temperament, delinquency, and mental illness. His reports on physique, health, and longevity, followed in the surviving veterans of the Spanish-American war (1898), and on the later careers of 200 delinquent boys first studied 25 years ago, will be completed by his colleagues.

Sheldon's studies of some biological underpinnings of behaviour offered a much-needed counterbalance to a psychology one-sidedly emphasising learning and environment. Psychology regarded this offer doubtfully, though the term *somatotyping* found currency in labelling many sorts of physique appraisal methods, much as the term *psychoanalysis* was misapplied to all sorts of appraisal and treatment methods, and even "schools" of

somatotyping developed, like the schools of psychoanalysis (Sheldon found this comparison odious).

A keen observer, Sheldon was thoroughly convinced of the value and accuracy of his observations—an asset in a pioneer researcher, a problem to academic psychologists mistrustful of personal judgments. His irreverence for some of psychology's sacred cows, and his schoolboy's sense of mischief combined with a talent for finding just the right parallel in nature to point up a description of a human structure or action, have needed many a colleague. But Sheldon enjoyed his life. A seven-days-a-week worker, a diner at cafeterias because he could not stand the delays and pretentiousness of restaurants, an inveigher against the poisons in modern life, he was also wholehearted in his appreciation of an idea, a friend, a sparrow on his windowsill, an old coin. (Numismatists know him as the author of the standard work classifying early American cents.) His work cleared and broadened one roadway into the study of human biology and behaviour that had been an overgrown trail.

Richard N. Walker

Arthur C. Hardy

ARTHUR C. HARDY, Professor of Physics at the Massachusetts Institute of Technology and inventor of the first recording spectrophotometer, died on 31 October at the age of 81.

His specialist interests were in optics and photography, and after graduating at the University of California in 1917, he immediately became involved in photography in the first world war when he served in the American Expeditionary Force as a Commanding Officer in the Photographic Section of the U.S. Army. After the war he spent two years at the Kodak Research Laboratories before taking up an appointment in 1922 as Assistant Professor in Optics and Photography at MIT, where he spent the remainder of his professional life, becoming successively Associate Professor, full Professor and, in 1961, Emeritus Professor.

He played some part in the development of sound recording on film, while in 1930, in collaboration with Professor S. F. Brown, he developed an electric organ which was intended to reproduce the sound of any musical instrument. It is, though, with his famous recording spectrophotometer that his name will always be associated, since it is fair to say that this instrument revolutionised industrial colour measurement.

Until then, spectral transmission and reflection measurements were made with visual instruments and the observations were extremely laborious and were often impossible because of

shortage of light. The recording of a spectral reflection curve through the visible spectrum in the course of only a few minutes meant that it now became a commercial proposition for the colour industries to determine the key property of their products, namely the spectral absorption of a dye or pigment.

The instrument has really had a very remarkable history. It was developed in the 1920s at MIT and a fascinating account of how the design evolved was given by Professor Hardy in 1938. (*History of the Design of the Recording Spectrophotometer*, *J. opt. Soc. Am.* **28**, 360–364; 1938.)

A number of the MIT staff participated in the project and a major element in its success was the use of an optical attenuator, a train of polarising prisms, to balance the light reflected from the sample against the light reflected from a reference white. The photoelectric cell, which was in those days a rather uncertain device, could therefore be relegated to the role of a null detector. In more recent recording spectrophotometers, on the other hand, the measurement is usually obtained by comparing the photocurrents themselves using a ratio-recording potentiometer or similar device. Yet the Hardy instrument is still holding its own against all competitors and is still regarded by many users as the standard instrument for colour measurement.

It was produced commercially by the American General Electric Company

as the G.E. Spectrophotometer, but it might have had an early rival from Westinghouse, since in 1930 I was involved, as a research engineer with Westinghouse in Pittsburgh, in discussions about the production of a competitor. These were not, however, followed up. It is now manufactured by the Diano Corporation as the Diano-Hardy Spectrophotometer and, naturally enough, includes a number of modifications and accessories although the basic design is still the same after nearly 50 years.

A further contribution which Professor Hardy made to colour measurement was the publication in 1936 of the *Handbook of Colorimetry*, prepared under his direction by a team drawn from the staff of MIT. This was the first book on colorimetry to appear following the establishment, by the Commission Internationale de L'Eclairage, of the 1931 system of colour specification based on tables defining the colour-matching characteristics of a standard observer. The many charts and tables in the Handbook provided an excellent introduction to the CIE system and undoubtedly speeded up the use of the system for colour standardisation and as a tool in the colour industries.

Professor Hardy received a number of honours, including the Frederick Ives Medal of the Optical Society of America. He also served as President of the Society from 1935 to 1937 and as Secretary from 1940 to 1957.

APPOINTMENTS VACANT

university of wales
**university
college of
swansea**

Chair of Geography

The Council of the College invites applications for the appointment of a Professor of Geography from August 1, 1978, or as soon as possible thereafter, consequent upon the retirement of Professor W. G. V. Balchin.

Further particulars may be obtained from the Registrar/Secretary, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom applications (10 copies) should be returned by February 28, 1978. 976(A)

UNIVERSITY OF SOUTHAMPTON FACULTY OF MEDICINE HUMAN REPRODUCTION AND OBSTETRICS

Applications are invited for the permanent post of Experimental Officer in Human Reproduction and Obstetrics. The person appointed will be expected to be in charge of the laboratories and to undertake a wide range of interesting experimental projects for the Unit. Candidates should have practical laboratory experience in Biochemistry/Endocrinology and research experience to Ph.D. level will normally be required. Salary scale: £2,904 to £4,811 (under review). The initial salary will depend on qualifications and experience.

Further particulars may be obtained from Mr. C. W. L. Swann, The University, Southampton SO9 5NH (to whom applications (4 copies from United Kingdom applicants) should be sent not later than January 27, 1978. Please quote ref: 85/A/N. 965(A)

TECHNICIAN

required in the Department of Oral Immunology and Microbiology for one year in the first instance with some experience in immunology and/or microbiology for research into the immune responses to microbial agents in immunodeficient children. Salary for qualified Technician not less than £2,982 plus £354 London Weighting.

Apply in writing, stating age and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. I.M.5. 973(A)

UNIVERSITY OF HULL SCIENTIFIC ASSISTANT

Applications are invited for the position of RESEARCH ASSISTANT to participate in research on the role of the thymus in embryonically induced transplantation tolerance. The work, which is funded by the M.R.C. for two years, will be on amphibians and will start as soon as possible. Previous research experience in developmental biology, cell biology, or immunobiology would be an advantage. Salary in accordance with age and qualifications up to an initial maximum of £3,582 per annum. Applicants with suitable qualifications in the biological sciences should write to Dr M. J. Manning, Department of Zoology, University of Hull, HU6 7RX, before February 1, 1978, and should include a full curriculum vitae and the names of two referees. 985(A)

CENTRAL ELECTRICITY GENERATING BOARD RESEARCH DIVISION BERKELEY NUCLEAR LABORATORIES RESEARCH OFFICERS

Applications are invited from Chemistry, Engineering and Physics Graduates for vacancies at Berkeley Nuclear Laboratories.

The Laboratories are situated on the banks of the River Severn mid-way between Bristol and Gloucester. Successful candidates would be joining research teams contributing to the successful and safe operation of Board's plant both nuclear and conventional.

Salaries for these appointments will be within the following grades of the National Joint Board Agreement, according to age and experience:

Band 2 £5,160 to £6,310/£6,910
Band 3 £4,410 to £5,760
Band 4 £2,610 to £4,860

Per annum plus £120 per annum Allowance plus relevant Salary Supplements.

Applications stating age, qualifications, experience, present position and salary, should be forwarded to the Personnel Officer, Berkeley Nuclear Laboratories, Berkeley, Gloucestershire GL13 9PB not later than January 28, 1978.

Please mark envelopes "Confidential" and quote Vacancy Notice Number: BNL 33/77. 1001(A)

ULSTER MUSEUM Botanic Gardens Belfast

Applications are invited for the following posts:

(1) ASSISTANT KEEPER ZOOLOGY

The person appointed will be responsible to the Keeper of Botany and Zoology for all matters pertaining to the vertebrate collections. This will include the curation of the collections; expansion of the collections by purchase or field collecting; answering of academic and public enquiries; dealing with the 'media' on vertebrate matters; preparation of popular and academic publications and preparation of public displays in conjunction with a design team.

The person appointed will also be expected to carry out research on an aspect of vertebrates relevant to the work of the Department.

Salary:

Assistant Keeper I £4404-£7109 per annum
Assistant Keeper II £2395-£3900 per annum
Plus supplements in each case of between £443 and £521 per annum.

An honours degree in Zoology is a requirement, and appointment at Assistant Keeper I is normally dependent upon the applicant being 30 years of age and having had considerable museum experience.

(2) SENIOR GRAPHIC DESIGNER

The person appointed will hold a senior position within a team of designers involved in the structure and graphics of exhibitions and displays.

Candidates must hold a recognized graphic design qualification and have at least three years' experience in their own field of work. A knowledge of three-dimensional design is essential.

Salary:

Graphics Officer IV £2425 (age 21)—£2970 (age 27) to £3450.

Plus supplements of between £443 and £521 per annum.

Application forms for these posts may be obtained from the Administrative Officer, Ulster Museum, Botanic Gardens, Belfast BT9 5AB.

Closing date for receipt of completed application forms: Monday, 23rd January, 1978.

998(A)

CSIRO AUSTRALIA Postdoctoral Research Fellow/ Research Fellow

Division of Process Technology North Ryde, N.S.W.

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,300 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: Chemical Engineering/Fuel Technology

General: In order to accelerate the introduction of fluidized-bed combustion of coals into Australia, the Division intends to expand its research effort in this area and seeks a suitable qualified scientist who wishes to make a significant contribution.

Duties: Research will be particularly concerned with the combustion characteristics of Australian coals, the influence of inorganic constituents and the implications of these with respect to the design and operation of fluidized-bed combustors.

Qualifications: A Ph.D. or equivalent research experience in Chemical Engineering, Fuel Technology or Applied Science. Previous experience in high temperature research, especially combustion or fluidized-beds, an advantage.

Salary: Research Scientist or Senior Research Scientist: A\$14,292 to A\$20,822 p.a.

Tenure: Fixed term of three years.

Applications (in duplicate), stating **FULL** personal and professional details, the names and addresses of at least two professional referees, and quoting reference number **588/19** should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, LONDON WC2R 3EH by **10th February 1978**. Applications in U.S.A. and Canada should be sent to: The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON D.C. 20036 U.S.A. 995(A)

PLANT SYSTEMATIST

Applications and nominations are invited for a tenured Curator-Professorship in the Arnold Arboretum and the Gray Herbarium, Harvard University. Position involves teaching, administrative duties in connection with the combined herbaria of the Gray Herbarium and Arnold Arboretum, and research. A broadly trained herbarium-oriented systematist with interest and ability in administration and demonstrated ability in teaching and systematic research is sought for this position in a stimulating academic environment. Position effective July 1, 1979.

Letters of application or nomination with resume and three references should be sent by February 28, 1978, to Professor C. E. Wood, Harvard University Herbaria, 22 Divinity Avenue, Cambridge, Mass. 02138.

An Affirmative Action/Equal Opportunity Employer.

1012(A)

UNIVERSITY OF LONDON KING'S COLLEGE SPECTROSCOPY ASSISTANT

Applications are invited for the above Technician Grade 5 post in the Physics Research Department to work mainly for the Infra-Red and High Pressure Groups. Duties will include: Crystal growing, operation of Infra-Red and Laser Raman Spectrometers, low temperature crystals and high pressure equipment and glass blowing techniques. Initial instruction will be given if required. Minimum qualifications H.N.C. or equivalent plus relevant experience. Salary £3,651 p.a. (inclusive) rising to £4,185 p.a. (inclusive). 4 weeks annual holiday. Contributory pension scheme. Apply in writing with full details: The Head Clerk, Ref. 191106/N, King's College London, Strand WC2R 2LS.

1003(A)

EQUINE RESEARCH STATION ANIMAL HEALTH TRUST NEWMARKET

Microbiologist, preferably with postgraduate qualifications — Dip.Bact. and/or Ph.D., required to join research team investigating Contagious Equine Metritis. Initially the biology and growth characteristics of the micro aerophilic organism are to be studied and collaborative investigations undertaken to improve methods of diagnosis. Further work will involve organisms inhabiting the equine genitalia in health and disease. The appointment will be for three years with a possibility of permanency.

Salary scale in the range £6,489 to £7,509 depending upon experience and qualifications. There is some urgency in making the appointment and applications giving full address plus two referees should reach the Director, Animal Health Trust, Equine Research Station, P.O. Box 5, Balaton Lodge, Snailwell Road, Newmarket, Suffolk CB8 7DW (telephone number 0638-61111), before January 27, 1978.

957(A)

Charing Cross Hospital DEPARTMENT OF MEDICAL PHYSICS BASIC GRADE PHYSICIST

Applications are invited for the above vacancy in this teaching hospital. Applicants should have a first or second class Honours degree in Physics. They will be mainly concerned with the uses, measurement and application of radiations in the medical field. They will also be expected to participate in the development of clinical instrumentation.

Previous experience is desirable, but not essential, and need not be in the medical field.

Salary is related to qualifications and experience, and is in accordance with Whitley Council Agreements, in the range of £3,090 to £4,258 inc., or £3,540 to £4,258 inc.

Application forms and further details may be obtained from the District Personnel Department, Charing Cross Hospital, Fulham Palace Road, London W6 8RF. Tel: 01-748 2040 ext. 2997. Closing date for return of applications February 3, 1978.

972(A)

CHEMICAL ENGINEERING

Applications are invited for appointment as Assistant Professor in Chemical Engineering. (Associate rank may be considered for an outstanding candidate). Qualifications required are a Ph.D. (or equivalent) in Chemical Engineering with research or industrial experience in fluidized reactor engineering. The successful applicant will be required to teach graduate and undergraduate courses in chemical engineering, including undergraduate core courses; and to conduct research and supervise graduate students in fluidized reactor engineering. The appointment is effective July 1, 1978. Closing date for applications is April 15, 1978. Applications including curriculum vitae and names of three referees may be sent to:

G. F. Chess, P.Eng.
Acting Dean
Faculty of Engineering Science
The University of Western Ontario
London, Ontario, Canada
N6A 5B9

960(A)

THE UNIVERSITY OF TORONTO

DEPARTMENT OF BOTANY

Applications are invited for a tenure-stream position as Assistant Professor in the Department of Botany. The position will be filled either by a plant virologist or by a higher plant taxonomist; candidates from both disciplines are invited to apply. A doctoral degree will be required, with commensurate research and teaching experience. The starting date for the post will be July 1, 1978. The salary range for Assistant Professor is currently \$15,900 to \$27,100, with starting salary determined by experience.

Further particulars can be obtained from Professor T. C. Hutchinson, Chairman, Department of Botany, University of Toronto, Toronto M5S 1A1, Canada, to whom applications and the names and addresses of three referees should be sent before March 1, 1978.

1013(A)

The University of Sheffield DEPARTMENT OF LANDSCAPE ARCHITECTURE EXPERIMENTAL OFFICER

Applications are invited for the above appointment to assist with the development of project teaching in courses for landscape architects up to postgraduate and professional levels. There are also opportunities to take part in departmental research. A scientific background with a postgraduate qualification or experience of landscape design, planning, conservation or landscape management is required. Salary in the range £2,904 to £3,547 on the OR 1B scale £2,904 to £4,190, with superannuation provision. Further particulars from the Registrar and Secretary, The University, Sheffield S10 2TN to whom applications (5 copies), should be sent by March 1, 1978. Quote Ref. R.61/G.

989(A)

MEDICAL RESEARCH COUNCIL TECHNICIAN/RESEARCH OFFICER

There is a vacancy for a Technician/Research Officer to work in the genetic analysis of human lymphoblastoid cell lines with particular emphasis on their surface antigens and the production of immunoglobulins *in vitro*.

Applicants should have H.N.C. or a degree in a relevant biological subject and experience in tissue culture work would be an advantage.

Salary, dependant upon grade, would be on a scale £2,511 to £3,738 or £2,790 to £3,936 both plus pay and variable pay supplements. The post is permanent and superannuable and conditions of employment are very good.

Applications in writing and including the names, etc., of two referees to the Administrative Officer, M.R.C. Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU, to arrive by January, 1978.

1021(A)

UNIVERSITY OF RHODESIA
LECTURER/
SENIOR LECTURER
in the
DEPARTMENT OF GEOLOGY

Applications are invited for appointment to Senior Lecturer/Lecturer in the Department of Geology. Applicants should have at least an honours degree in Geology and be competent to teach Sedimentology. Experience in one or more of the fields of structural, metamorphic and economic Geology would be an added recommendation.

Salary Scales (Approx. Sigs. Equiv.):
Senior Lecturer—£7,352 by 278 to £7,630 by 288 to £7,918 by 298 to £9,706; Lecturer Grade I—£6,675 by 248 to £7,667; Lecturer Grade II: £4,118 by 218 to £5,208 by 248 to £6,448.

Permanent Pensionable Terms:
Family passages and allowance towards transport of effects on appointment. Installation loan of up to half of one year's salary if required. Unfurnished University accommodation guaranteed for a period of at least three years for persons recruited from outside Rhodesia. Sabbatical Leave and Triennial visits with travel allowances. Superannuation and medical aid schemes.

Short-term Contracts: Family passages and allowance towards transport of effects. Assistance with accommodation for persons recruited from outside Rhodesia.

Applications: Six copies giving full personal particulars (including full name, place and date of birth, etc.), qualifications, experience and publications and names and addresses of three referees, should be submitted by January 31, 1978, to the Senior Assistant Registrar (Science), University of Rhodesia, P.O. Box MP 167, Mount Pleasant, Salisbury, Rhodesia. Overseas applicants should send a copy of their applications to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom conditions of appointment may be obtained.

British subjects considering applying for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (telephone 233 4143) or their nearest British Consular Office. 1025(A)

Nature Conservancy Council
SCIENTIFIC OFFICER/
HIGHER SCIENTIFIC
OFFICER

Salary £2,592 to £4,032 (S.O.), £3,745 to £4,976 (H.S.O.) Starting salary may be above the minimum depending on age, qualifications and experience. Promotion prospects to £6,300 and above.

Applications are invited for the following post:—

ASSISTANT REGIONAL OFFICER—
CLWYD

The A.R.O. will be based at the County Planning Office at Mold and will represent the N.C.C. in the county of Clwyd which, with Gwynedd, comprises the North Wales Region of N.C.C. Duties of the post will include the conservation of Sites of Special Scientific Interest, provision of advice on wildlife conservation to planning authorities and other official bodies, landowners and the voluntary interests. The Officer appointed will also organise and conduct ecological surveys and liaise with the public, including lecturing and field visits and assist in the preparation of leaflets.

Candidates should normally be under 30 years of age with a degree (or equivalent) in Geology, Zoology, Botany or Geography. A current driving licence is essential.

Application forms and further particulars are available from Miss L. Bull, Recruitment Section, Nature Conservancy Council, P.O. Box 6, George Street, Huntingdon, Cambs. PE18 6BU (Tel. Huntingdon (0480) 56191 ext. 277). Please quote reference number: E2/18/17.

Closing date for completed application forms: February 3, 1978. 979(A)

ICI Central Toxicology Laboratory

Research Assistant

This Laboratory provides advisory and experimental services to ICI Ltd, for the control of toxic hazards in manufacturing processes and in other fields of growing importance, such as the development of pesticides and food additives. Emphasis is placed on improving and assessing methods for studying the biological effect of foreign compounds and upon understanding mechanisms of toxicity. The provision of toxicological information, prior to product clearance and registration in many countries, is a major activity undertaken by the Laboratory on behalf of the ICI group.

We are looking for a Research Assistant with a degree or equivalent in biochemistry. He/she will join a small applied biochemistry group whose remit is to contribute to the development of both new predictive approaches and routine procedures for use in the determination of the acute toxicological effects of ICI compounds. Specifically, the

main interest of this group lies in the assessment of primary irritancy of the skin. The job holder will have the ability to work on his/her own initiative with the flair and skill to adapt, improve and modify experimental techniques as conditions demand.

Although not essential, previous practical experience in enzyme kinetic measurements, spectrophotometry and the use of radioisotopes would be an advantage.

Requests for application forms, quoting Reference RA/AT/GO, should be addressed to:

Miss S. C. Carson
Personnel Officer—
ICI Limited
Central Toxicology Laboratory
Alderley Park
Nr. Macclesfield, Cheshire

OVERSEAS CANDIDATES SHOULD ONLY
APPLY IF THEY HAVE A PLANNED VISIT TO
THE UK WITHIN THE NEXT TWO MONTHS.

1018(A)

**THE UNIVERSITY
OF LEEDS**

**DEPARTMENT OF
MICROBIOLOGY**

Applications are invited for the post of LECTURER, available from October 1978. The successful candidate will be expected to assist in teaching bacteriology at all levels of the B.Sc. course in Microbiology. An interest in medical bacteriology (this would be taken to include those with a record of research achievement in fundamental bacteriology interested in collaborative research with clinical bacteriologists) or in bacterial physiology would be particularly welcome, but is not essential. Salary on the scale for Lecturers £3,333 to £6,655. Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 96/7D. Closing date for applications, February 3, 1978. 990(A)

**FACULTY POSITION—
PLANT BIOCHEMIST**

Applications are requested for an appointment as ASSISTANT PROFESSOR OF BIOCHEMISTRY in the tenure track at the University of California, Riverside, effective Summer 1978. Applicants should have demonstrated ability in research in plant biochemistry and the capability to develop a vigorous research program in this area. This individual will be expected to teach a course in plant biochemistry at the upper division/graduate level and participate in other teaching activities of the department. Candidates should send curriculum vitae, a statement of their current and future research interests and ask three scientists familiar with their work to send us letters of recommendation. Applications will be accepted until March 10, 1978 or until a suitable candidate is located. Address correspondence to: SEARCH COMMITTEE, PLANT BIOCHEMIST, Department of Biochemistry, University of California, Riverside, CA 92521. The University of California is an Equal Opportunity/Affirmative Action Employer. Minority and women candidates are encouraged to apply. 969(A)

**M.R.C. NEUROCHEMICAL
PHARMACOLOGY UNIT
NEUROANATOMIST**

A vacancy exists for a non-clinical scientist to carry out neuroanatomical research, with an emphasis on studies of the distribution of various neurotransmitters and drug receptors in mammalian CNS. The person appointed would be expected to develop their own lines of research in this area, and to collaborate with other members of the scientific staff. Modern light and electron microscope facilities are available, and substantial quantities of human post-mortem brain tissue can be made available for research purposes if desired.

Candidates should hold a Ph.D. in neuroanatomy or a related subject and experience with modern anatomical and histochemical techniques would be desirable. The position is available from August 1, 1978 and would be initially for a term of 5 years.

Salary depending on age and experience, within the range £4,190 (to £5,219) or £5,423 (to £6,655). M.R.C. conditions of service. The post is superannuable.

Applications in writing please to Dr L. Iversen, Director, M.R.C. Neurochemical Pharmacology Unit, Department of Pharmacology, Medical School, Hills Road, Cambridge CB2 2QD. Closing date for applications, February 17, 1978. 996(A)

AN FORAS TALUNTAIS
GRADUATE IN AGRICULTURAL SCIENCE OR
VETERINARY SCIENCE

Required for research on carcass composition with particular reference to the assessment of carcass quality.

ESSENTIAL: An Honours University degree, or equivalent, in Agricultural Science or a University degree, or equivalent, in Veterinary Science.

DESIRABLE: Suitable research experience and/or experience in Animal Husbandry.

Appointment up to and including Senior Research Officer level, depending on qualifications and experience. Non-contributory Pension Scheme with provision for Widows' and Orphans' pensions.

Application form and further particulars may be obtained from The Personnel Department, (Ref: MRD2), An Foras Taluntais, Headquarters, 19 Sandymount Ave., Ballsbridge, Dublin, 4. (Phone 688188). Latest date for receipt of completed forms Monday January 30, 1978. 962(A)

TECHNICIAN

required to join a research team investigating certain aspects of mammalian meiosis. H.N.C. or equivalent qualification required. Applications to the Administrative Assistant, Paediatric Research Unit, The Prince Philip Research Laboratories, Guy's Tower, London Bridge, SE1 9RT. 1008(A)

THE UNIVERSITY OF BRITISH COLUMBIA

In anticipation of increased activity in coal exploration, production and utilization within the Province of British Columbia, the University of British Columbia, a government funded institution which provides instruction and research opportunities to 23,000 students, is expanding its coal activities. A new coal research laboratory is scheduled for completion in 1978 and the following faculty appointments are expected to be made in August, 1978.

Within the Department of Mineral Engineering:

Coal Processing—Working in conjunction with three mineral processing faculty members, the appointee can expect to lead the coal processing activities of the department by providing appropriate instruction and research direction to undergraduate and graduate students.

Applicants are expected to be holders of advanced degrees who, through participation in coal-processing plant design and operation, and/or coal processing research, are well versed in current technology.

Mine Services—In collaboration with three mining engineer faculty members, the appointee will engage in the teaching and research aspects of mine ventilation, materials handling systems, and the control of dust and noxious gases. The appointee will be a graduate engineer who, through appropriate underground mining experience, is conversant with modern practice in the specific fields mentioned above. Coal mining experience is a decided asset for this appointment.

Rock Mechanics—The appointee will hold an appropriate advanced degree and will be oriented to the measurements of in-situ rock stress distributions and the design of underground openings in strata-bound sequences. In cooperation with three mining engineer faculty members, the appointee will be responsible for undergraduate instruction and graduate studies in applied rock mechanics. Currently the department possesses a variety of rock properties measurement equipment and has direct access to an extensive computer facility.

Within the Department of Geological Sciences:

Coal Geologists—The department is seeking a geologist who will develop a coal geology program that integrates with the coal activities in Mineral Engineering. The appointee will be involved in teaching coal geology, the supervision of graduate students, and a research program in geologic aspects concerned with mine development, such as structure, stratigraphy, correlation, petrology, and geo-statistics. A Ph.D., in hand or pending, and field experience in coal geology are essential. It is expected the appointment will be made at the Assistant or Associate level.

Applicable salary ranges are as follows:

Assistant Professor	\$20,000—\$27,000 per annum
Associate Professor	\$27,000—\$32,000 per annum
Full Professor	\$30,000—\$35,000 per annum

Enquiries, or applications accompanied by a full curriculum vitae and the names of three referees, should be directed as follows:

a) for positions within Mineral Engineering

The Head,
Department of Mineral Engineering,
University of British Columbia,
VANCOUVER, B. C., Canada V6T 1W5

b) for the position within Geological Sciences

Dr. W. H. Matthews
Chairman, Coal Committee
Department of Geological Sciences,
University of British Columbia,
VANCOUVER, B. C., Canada

This announcement should not be construed as a commitment by U.B.C. to make appointments in rigid adherence to the above descriptions. 926(A)

Rothamsted Experimental Station

Harpden, Herts. AL5 2JQ ASSISTANT MANAGER (Male or Female)

required for mainly arable 800 acre farm. Duties will be mainly concerned with the provision of technical information and services to field staff working on farm and field experiments. The successful applicant will be required to assist with office and farms organisation and to liaise with scientific staff.

Qualifications: Pass degree (Agric.), H.N.C., or equivalent with at least 5 years' relevant post qualifying experience.

Appointment in grade of Higher Scientific Officer, salary range £3,776 to £4,976 including current pay supplements. Non-contributory superannuation.

House available to rent.

Apply in writing to the Secretary giving names and addresses of two referees and quoting ref. 344 by January 3, 1978. Further details on request. 980(A)

ECOLOGIST-ASSOCIATE DIRECTOR, U.C.L.A.

Applications are invited from highly qualified ecologists to become Chief of Division of Environmental Biology and Associate Director of the Laboratory of Nuclear Medicine and Radiation Biology. The position carries a joint appointment, presumably at the full professor level, in the Department of Biology, and undergraduate and graduate teaching responsibilities. Research interests should be in quantitative ecology and applicants should be interested in resolving environmental problems related to energy technologies because the Laboratory's research is funded primarily by the Department of Energy (formerly E.R.D.A.).

Send letters of inquiry or application, including curriculum vitae, description of research and teaching interests, and names and addresses of three referees before February 15, 1978 to Director's Office, Laboratory of Nuclear Medicine and Radiation Biology, University of California, 900 Veteran Avenue, Los Angeles, California, 90024. An equal opportunity/affirmative action employer. 902(A)

AN FORAS TALUNTAIS

GRADUATE IN CHEMISTRY OR BIO-CHEMISTRY

Required by An Foras Taluntais in its Cereal Technology Department, Kinsealy Research Centre, Malahide, Co. Dublin. The appointee will be engaged in a research programme on cereal technology and will work in close liaison with the milling and baking industries.

ESSENTIAL: Honours University degree, or equivalent, majoring in Chemistry or Biochemistry.

DESIRABLE: Suitable experience in the cereal industries.

Commencing salary and level of appointment will depend on qualifications and experience. Application forms and further particulars from the Personnel Department, Headquarters, 19 Sandymount Ave., Dublin, 4. (Tel: 01-688188). Latest date for receipt of completed application forms Friday January 27, 1978. 964(A)

UNIVERSITY OF OXFORD

Microbiology Unit DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT— Ref. B14

There is a vacancy for a post-doctoral biochemist or microbiologist to work on bacterial sporulation. The appointment, which will be for one year in the first instance, on the scale £3,333 to £5,627, may be extended for a further period of two years and there is provision for U.S.S. membership.

Applications, which should include relevant details and the names of two referees, should be sent before February 28, 1978 to Professor J. Mandelstam, Microbiology Unit, Dept. of Biochemistry, South Parks Road, Oxford OX1 3QU.

DEPARTMENTAL DEMONSTRATORSHIP— Ref. B15

It is proposed to appoint a Departmental Demonstrator from October 1, 1978. The salary will be on the scale £3,333 to £3,833, according to qualifications and experience and with membership of U.S.S. The appointment is for a period not exceeding 3 years. The successful candidate will be expected to take part in departmental teaching and to conduct his or her own research.

Applications (3 copies) including the names of two referees, should be sent to: The Administrator, Department of Biochemistry, South Parks Road, Oxford OX1 3QU not later than February 28, 1978. 863(A)

New Zealand UNIVERSITY OF CANTERBURY Christchurch

Applications are invited for the following positions:

LECTURER OR SENIOR LECTURER IN CIVIL ENGINEERING

Applicants should have a good degree and a specialised knowledge in the history of civil engineering. An interest in structural mechanics or engineering materials would also be an advantage. Applications close on April 30, 1978.

LECTURER IN ZOOLOGY

Applicants should be qualified to teach undergraduate genetics and will be expected to lecture and conduct laboratory classes in this branch of zoology. Applications close on February 28, 1978.

The salary for Senior Lecturers is on a scale from NZ\$13,424 to \$15,411 (bar), \$16,546 per annum and for Lecturers is on a scale from NZ\$10,585 to \$12,969 per annum.

Particulars, including information on travel and removal allowances, study leave, housing and superannuation, may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 1026(A)

UNIVERSITY OF YANNINA

SCHOOL OF MEDICINE

"VACANT CHAIRS IN GENERAL BIOLOGY AND BIOCHEMISTRY"

The School of Medicine at the University of Yannina would like to inform that shortly they will be advertising in the Government's Official Gazette two vacant chairs, one in General Biology and one in Biochemistry.

For further information, concerning details and the exact date of publication of the vacancies in the Government's Official Gazette, the applicants should contact the Secretariat of the School of Medicine, University of Yannina.

Tel: 0651 21802 Monday-Saturday between 8.00 a.m.-2.00 p.m. 935(A)

THE OPEN UNIVERSITY

RESEARCH FELLOW IN EARTH SCIENCES

The Research Fellow will assist Dr P. W. Francis in continuing studies of recent volcanism in the Central Andes. The work will be concerned with studies of large volume ignimbrites and their source structures and other volcanic problems, and will involve extensive field work. Applicants should have a Ph.D. and research experience in volcanology, preferably on recent pyroclastic flows. They should also have experience of working in remote areas. Knowledge of Spanish is an advantage. The Fellowship is funded by the N.E.R.C. and is for a period of three years commencing as soon as possible, after January 1, 1978.

The salary will be in the range £3,333 to £3,761 p.a. Further particulars and application forms are available from the Personnel Manager (RFE2) P.O. Box 75, The Open University, Walton Hall, Milton Keynes, MK7 6AL. Telephone: Milton Keynes 63868. Closing date for applications January 26, 1978. 1005(A)

CHEMISTRY LIBRARIAN

LIBRARIAN II or III

Available July 1, 1978. Responsible for the management and operation of the Chemistry/Biochemistry Library. Advanced degree or relevant experience in the subject field and M.L.S. preferred; relevant library experience desirable. Salary in a range having base of \$13,000 (L-II) or \$15,100 (L-III) but without a ceiling. Send résumé, three letters of recommendation and transcripts, by February 15, 1978, to:

Chemistry Librarian Search Committee,
c/o Maria G. Larson
Princeton University Library
Princeton, N.J. 08540.
Equal opportunity/affirmative action employer. 927(A)

UNIVERSITY OF THE WEST INDIES JAMAICA

Applications are invited for the following posts:

LECTURER/ ASSISTANT LECTURER in the DEPARTMENT OF BIOCHEMISTRY

Duties of the appointee will include lecturing and demonstrating to classes of undergraduates in both the Medical and Natural Sciences Faculties. Preference will be given to candidates with medical qualifications. The appointment will run until September 30, 1979.

Salary scales: Senior Lecturer J\$15,339 to J\$19,326 p.a.; Lecturer (Medical) J\$11,262 to J\$15,015 p.a.; (Non-Medical) J\$8,913 to J\$13,917 p.a.; Assistant Lecturer (Medical) J\$9,102 to J\$9,936 p.a.; (Non-Medical) J\$7,236 to J\$8,412 p.a. (£1 sterling=J\$2.34.) F.S.S.U. Study and Travel Grant. Unfurnished accommodation will be let by the University at a rental of 10% of full passages (at approved rates) on appointment and on normal termination.

Detailed applications (three copies) giving full particulars of qualifications and experience, date of birth, marital status and the names and addresses of three referees should be sent as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Further particulars of the post are available from the same source. 1017(A)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND

Pharmacologists with a Ph.D. and/or M.D. degree are invited to apply for a faculty position at the Faculty of Medicine, Memorial University of Newfoundland. The duties will include contributing to the teaching of pharmacology in an integrated medical curriculum as well as some pharmacology teaching to science students and to graduate students. Candidates should have a broad background in general pharmacology with a major interest in drug kinetics, toxicology, drug metabolism or biochemical pharmacology and will be expected to have or to develop a research program. The Faculty of Medicine has recently moved into a new Health Sciences Complex located on the Memorial University Campus, and will soon be joined by the St. John's General Hospital.

Academic rank and salary will be commensurate with experience and qualifications. The position will be available from September 1978 or by negotiation. The application deadline is March 10, 1978. Application, including curriculum vitae and the names and addresses of three references, should be sent to: Dr R. S. Neuman; Chairman, Pharmacology Search Committee; Faculty of Medicine, St John's, Newfoundland, Canada A1B 3V6. 812(A)

HARVARD UNIVERSITY

seeks a biological anthropologist with a specialisation in paleoanthropology and human evolution, as well as a specialisation in human anatomy. This is for a permanent position as a full professor beginning in September 1978. The appointment is to be made jointly by the Department of Anthropology and the Department of Anatomy in the Harvard Medical School. Applicants must have a Ph.D. as well as teaching and research interests in these fields.

Kindly send curriculum vitae, references and publications to Ms Mary Clare Gubbins, Peabody Museum, 54A, Harvard University, Cambridge, Massachusetts 02138. Harvard University is an equal opportunity, affirmative action employer. 925(A)

BRITISH PHARMACOPOEIA COMMISSION

PHARMACIST

... to help maintain medicinal standards

The British Pharmacopoeia Commission is responsible for all published standards for articles used in both human and veterinary medicine. The successful candidate, based at the Commission's new laboratories at Canons Park, Middx, will be concerned with the physical pharmaceutical aspects of standards for the quality control of medicinal substances and preparations. The work will centre around investigating the formulation of official preparations (including laboratory manufacture of batches of material to evaluate their stability). It will also involve devising test methods for existing and new formulations and monographs, and preparing reports for technical committees.

For further details of the work, phone Mrs S Richens on 01-952 2311 ext 397 or 395.

Candidates (normally aged under 30) should have a degree or equivalent in Pharmacy and have had experience in pharmaceutical research, product formulation or quality control.

Appointment will be as Higher Scientific Officer (£4,030 to £5,250). Starting salary according to qualifications and experience. There is a non-contributory pension scheme.

For further details and an application form (to be returned by 3 February 1978), write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote reference SB/10/KD. 1002(A)

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF BIOCHEMISTRY RESEARCH ASSOCIATE

Applications are invited from post-doctoral biochemists, molecular biologists or microbial geneticists to join a small group investigating DNA repair and genetic recombination in *Escherichia coli*. The project is supported by a grant from the Medical Research Council and the appointment will be for three years at a salary within the scale £3,333 to £5,627 (under review).

Enquiries and applications, which should include a curriculum vitae and the names of two referees, should be sent to Dr P. T. Emmerson, Department of Biochemistry, University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU (telephone 0632 28511, ext. 3434). 1015(A)

DEPARTMENT OF PHYSICS ASSISTANT PROFESSORSHIP

Subject to adequate funding, a position may become available July 1, 1978 in one of the following fields

QUANTUM OPTICS BIOPHYSICS

Salary depends on qualifications. The closing date for applications is March 31, 1978.

Exceptional candidates in other fields may be considered.

All correspondence should be addressed to:

Professor Luis de Sobrino,
Chairman,
Appointments Committee,
Department of Physics,
The University of British
Columbia,
2075 Westbrook Place,
Vancouver, British Columbia,
Canada V6T 1W5. 823(A)

THE DISTILLERS COMPANY LIMITED FERMENTATION BIOCHEMIST

The Yeast and Food Division of the Distillers Company Limited requires a graduate to work in their small scale Pilot Plant at Glenochil Technical Centre, Menstrie, Clackmannanshire. Studies carried out in this Pilot Plant include yeast strain selection work, process development and examination of raw materials.

Applicants, who should preferably be under 28 years old, must have a degree in microbiology, biochemistry or closely related subjects together with relevant postgraduate experience. One or two years commercial or research experience with yeast would be an advantage.

Further details together with an application form can be obtained by writing to:

The Yeast Research Manager,
Yeast and Food Division,
The Distillers Company Limited,
Glenochil Technical Centre,
MENSTRIE,
Clackmannanshire FK11 7ES.
1016(A)

ZOOLOGICAL SOCIETY OF LONDON

requires

RECORDERS FOR ZOOLOGICAL RECORD

a bibliography of the world's zoological literature.

For one vacancy in the Unit at Boston Spa, West Yorkshire, the ability to read and summarise Russian—preferably at degree level—is required. For a further vacancy which may be either at Boston Spa or in the Unit based at the British Museum (Natural History) in London, linguistic ability—while helpful—is not essential. For this post applicants should preferably possess a degree in Zoology or an allied subject.

Salary £2,737.50 on scale to £3,978.45 (including supplements). An additional allowance is payable in respect of the post to read Russian.

Application in writing, giving brief details of career to date and stating which vacancy is being applied for, should be made to the Managing Recorder, 44 High Street, Boston Spa, Wetherby, West Yorkshire LS23 6EA, by January 20. 1019(A)

QUEEN ELIZABETH COLLEGE

(University of London)
Campden Hill Road,
Kensington, London W8 7AH
TEMPORARY LECTURER
in Social Nutrition

Applications are invited for a Lectureship in Social Nutrition in the Food Science and Nutrition Department, to start October 1, 1978 or earlier and to last three years. The person appointed will be expected to organise and take some part in the teaching of courses dealing with the social, cultural and traditional factors that influence food choice, and, in addition, take part in the general teaching of nutrition.

Salary scale currently £3,355 to £6,655 plus £450 p.a. London allowance.

Further particulars and application forms may be obtained from the College Secretary. Closing date February 28, 1978. 991(A)

Director —Institute of Oceanographic Sciences

The Natural Environment Research Council (NERC) invites applications for the post of Director of the Institute of Oceanographic Sciences, which will shortly become vacant. The post is based at Godalming, Surrey.

The Institute in its present form was created by the Council in 1973 by bringing together under a single Directorate three previously separate NERC marine research establishments. These were the National Institute of Oceanography at Wormley, the Institute of Coastal Oceanography and Tides at Bidston (Birkenhead) and the Unit of Coastal Sedimentation at Taunton.

The work of the Institute covers the deep oceans, shelf seas and coastal and estuarine waters. Its research programme includes studies of ocean dynamics, currents, waves and tides; the geology of the sea floor; sedimentology; chemistry; and the biology of the deep oceans. To carry out its work at sea the Institute uses the vessels of the NERC research vessel fleet, especially RRS DISCOVERY.

An important function of the Institute is the development of scientific equipment and instrumentation for marine research, and the Institute has well-equipped engineering and electronic laboratories.

The annual expenditure of the Institute is at present £4.75m and receipts, mainly from research contracts undertaken for Government Departments and other organisations, are £2.5m.

The post calls for an outstanding marine scientist who can provide leadership in both the fundamental and applied aspects of the subject. The successful candidate must also have had experience in administration of research. The post carries the rank of Chief Scientific Officer (A) with a salary of £12,000 plus £208.80 Phase II pay supplement. There is a non-contributory superannuation scheme.

For application forms, please write to:

J. Hansford
Natural Environment Research Council
Falcon House, Fleming Way, Swindon SN1 2NG
quoting reference E2/B1/39. Closing date: 31 January 1978.

Research Council**

British Trust for Ornithology APPOINTMENT OF DIRECTOR

The British Trust for Ornithology is seeking a well qualified ornithologist or zoologist to promote the development of the Trust as a national centre for ornithology. The director will have primary responsibility for leading the scientific work of the Trust. The appointment will be made in the Civil Service P.S.O. Grade (£6,034 to £7,725).

Further particulars may be obtained from The Administrator, British Trust for Ornithology, Beech Grove, Tring, Herts. Closing date for applications will be January 31 1978. 997(A)

UNIVERSITY OF LEICESTER RESEARCH ASSOCIATE IN CHEMISTRY

An S.R.C. Postdoctoral appointment is available for a suitable candidate to study 'The Aqueous Chemistry of Alcohols and Sugars using N.M.R. and Infra-red Spectroscopy.'

The work is a combined study with Professor M. C. R. Symons and Dr W. Derbyshire of Nottingham University, and the initial salary will be £3,333 a year, starting as soon as possible.

For details, please contact Professor M. C. R. Symons, Department of Chemistry, The University, Leicester LE1 7RH. 1006(A)

AN FORAS TALUNTAIS GRADUATE IN CHEMICAL OR MECHANICAL ENGINEERING

Required for research on the bio-engineering problems associated with the handling, chilling, freezing and preservation of meat and meat products.

ESSENTIAL: An Honours University degree, or equivalent, in Chemical or Mechanical engineering.

DESIRABLE: Suitable experience, preferably in the food industry.

Appointment up to and including Senior Research Officer level, depending on qualifications and experience. Non-contributory Pension Scheme with provision for Widows' and Orphans' pensions.

Application form and further particulars may be obtained from The Personnel Department, (Ref: MRD3), An Foras Taluntais, Headquarters, 19 Sandymount Ave., Ballsbridge, Dublin, 4. (Phone 688188). Latest date for receipt of completed forms Monday January 23, 1978. 961(A)

M.R.C. CLINICAL RESEARCH CENTRE

(Northwick Park Hospital)

Watford Road, Harrow, Middlesex, HA1 3UJ

The division of immunological medicine (Head: G. L. Asherson) has three-year appointment for IMAGINATIVE SCIENTIST with biochemical or biological interests to study T suppressor cells and their assay in animals and man. Candidates may visit the department by telephoning G. L. Asherson, 01-864 5311, ext. 2692.

Applicants must have three years postgraduate experience.

Salary within the range £3,355 to £5,219 plus £450 London allowance.

Further details and application form obtainable from Mrs J. Tucker-Bull quoting ref. 118/1/4194. Closing date: January 31, 1978. 1020(A)

INSTITUTE OF TERRESTRIAL ECOLOGY A SCIENTIFIC OFFICER

is required at the Institute's Research Station at Bush Estate near Edinburgh to join a group studying the taxonomy of bryophytes. A sound botanical training with interest in taxonomy and preferably some knowledge of bryophytes is required. The curation of a small bryophyte herbarium is an essential part of the job.

Qualifications: A degree or equivalent in Botany or in an appropriate subject.

Salary and conditions of service: Appointment will be in the grade of Scientific Officer. The salary will be in the scale £2,149 to £3,527 per annum plus Phase I pay supplement of £313.20 per annum and 5% Phase II supplement of between £130.50 per annum and £208.80 per annum. Starting pay will be according to age, qualifications and experience. Non-contributory superannuation scheme.

The Natural Environment Research Council is not a Government Department but conditions of service are similar to those of the Civil Service.

Application forms and further details are available from:

Establishments Section
Institute of Terrestrial Ecology
68 Hills Road
Cambridge CB2 1LA
Telephone: (0223) 69745

Please quote reference Bush 133. Closing date for completed applications is January 30, 1978.

**NATURAL ENVIRONMENT
RESEARCH COUNCIL**
1028(A)

UNIVERSITY OF EXETER SOUTH-WEST ENERGY GROUP PHYSICIST/ENGINEER

Devon and Cornwall County Councils and the States of Jersey have founded an Energy Group in conjunction with the University of Exeter, Plymouth Polytechnic and the Camborne Royal School of Mines, charged with the study of energy matters relating to the South-West.

The Group wishes to appoint a Physicist/Engineer to undertake work in the solar energy field in the Department of Physics. He/she will be the second of a small interdisciplinary team, working at the University, whose output will be fed back to the local authorities as part of what is hoped will eventually become a long-term project. There will be liaison with other groups in the area and it is hoped that the project will be a continuing one.

The appointment will be for up to two years in the first instance starting on April 1, 1978. The salary at appointment will be dependent upon qualifications and experience within the range £3,333 to £4,607 p.a. subject to review. The post is superannuated. Applicants should hold at least a good honours degree.

Applications (five copies) together with the names of three referees, should be sent to Miss Doreen Watson, Administrative Assistant (Appointments), University of Exeter, Northcote House, Exeter EX4 4QJ, by January 31, 1978. 1009(A)

The University of Sheffield DEPARTMENT OF CHEMISTRY POSTDOCTORAL ASSISTANT

Applications are invited for the post of postdoctoral Assistant in an investigation of the synthesis of model enzyme systems related to chorismate synthetase. Tenable up to two years commencing as soon as possible and supported by S.R.C. Salary in the range £3,333 to £3,547 on Range IA with superannuation. Applications with the names of 2 referees should be made to Dr E. Haslam, Department of Chemistry, University of Sheffield, Sheffield S3 7HF. Quote Ref. R.60/G. 988(A)

UNIVERSITY OF ULM, WEST GERMANY LABORATORY OF IMMUNOLOGY, DEPARTMENT OF MICROBIOLOGY POSTDOCTORAL RESEARCH ASSISTANT IMMUNOCHEMISTRY/ BIOCHEMISTRY

Immunologists are invited to apply for a postdoctoral research assistantship to work on a project concerned with cell interactions in the immune response with special reference to humoral mediators. The position is at least for three years, will be open January 1, 1978 or later and has a salary according to qualification and experience (£12,900 to £13,600). Candidates should preferably have a Ph.D., a background in immunochimistry is essential. Applications, including curriculum vitae, a description of research experience, relevant reprints and the names and addresses of two referees should be sent to Dr H.-D. Flad, Laboratory of Immunology, Department of Microbiology, University of Ulm, P.O. Box 4066, D-7900 Ulm, West Germany. 868(A).

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London) DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY A TECHNICIAN

is required with experience of physical and chemical techniques to work with a team studying biomembrane structure and function. Some experience in electronics would be useful.

Salary on Whitley Council Scale. Application forms which are available from the School Secretary Royal Free Hospital School of Medicine, 8 Hunter Street London WC1N 1BF (telephone 01-837 5385, Ext. 8), should be returned by Friday, January 20, 1978. 994(A)

UNIVERSITY OF RHODESIA

Faculty of Science

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the following post within this Department:

CHIEF TECHNICIAN

The successful candidate will be responsible to the Head of Department for the department's technical services, equipment and staff. Prospective candidates must have one of the following qualifications or an approved equivalent and have had a minimum of five years relevant postqualification experience: (a) Diploma in Medical Laboratory Technology at Final Level, preferably in Clinical Chemistry; (b) City and Guilds Advanced Certificate in Biochemistry or Chemistry. In addition relevant experience in instrumentation, maintenance and electronics and proven administrative ability would be further recommendations.

Salary Scale (Approx. Sig. Equiv.): £4,719 by £74 to £6,911 or £7,158, depending on qualifications.

Pension and Medical Aid Schemes. Attractive Leave conditions. Family fares and allowance for transport of effects are available on appointment.

Applications: Six copies giving full personal particulars (including full name, place and date of birth, etc.), qualifications, experience and the names and addresses of two referees, should be submitted to the Assistant Registrar, Faculty of Science, University of Rhodesia, P.O. Box MP 167, Mount Pleasant, Salisbury, from whom further particulars may be obtained. Applications should reach him by not later than **January 31, 1978**.

British subjects considering applying for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (telephone 233 4143) or their nearest British Consular Office.

1024(A)

SWINBURNE COLLEGE OF TECHNOLOGY

(Melbourne, Australia)

LECTURER IN BIOPHYSICS

(Contract Appointment)

Applications are invited from graduates with a relevant higher degree in physiology, clinical biophysics or biomedical engineering and with clinical and/or research experience in cardiovascular physiology.

Teaching experience will also be considered in making the appointment.

The appointment will be by contract for three years duration including removal and repatriation expenses. Permanent appointment, during or at the expiration of the period, may be negotiated by mutual agreement.

The successful applicant will be involved in the undergraduate and postgraduate biophysics teaching programme with particular responsibility for the cardiovascular component of these courses. The successful applicant will also be encouraged to participate in an area of relevant applied research.

Swinburne College of Technology is a tertiary educational institution affiliated with the Victoria Institute of Colleges. The Department of Physics is a member department of the Faculty of Applied Science, and has responsibility for undergraduate courses in biophysics and instrumental science together with postgraduate programme in biophysics, biomedical instrumentation and instrumental science.

Salary: Lecturer II \$A14,631 to \$A16,748; Lecturer I \$A17,145 to \$A19,261 p.a.

Applications close February 18, 1978.

Further information about the position, conditions of employment and application procedure may be obtained from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF.

983(A)

IMPERIAL CANCER RESEARCH FUND

Bursaries for Training in Research

A small number of Bursaries will be awarded at the laboratories in Lincoln's Inn Fields for full-time studies leading to higher Degrees in research fields relevant to cancer, that include chemistry, cell and molecular biology. The awards will be tenable for three years from October 1, 1978 with a non-supernannable grant of £2,640 a year (subject to tax) and, in some cases, additional allowances.

Applications are invited from British subjects, normally resident in the U.K. and not over 25 years of age, who hope to obtain First or Upper Second class Honours Degrees in Science in 1978.

Further details and application forms are available from:

The Personnel Officer
Imperial Cancer Research Fund
Lincoln's Inn Fields
London WC2A 3PX

Completed applications should reach the Director of Research at the above address not later than February 14, 1978.

904(A)

UNIVERSITY OF AUCKLAND

(New Zealand)

Applications are invited for the following full-time position. Conditions of Appointment and Method of Application are available from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF, or from the Assistant Registrar (Academic Appointments) at the University of Auckland. Applications will be accepted at any time up to **February 28, 1978**. Candidates should note that at present all salaries are supplemented by a cost-of-living allowance of NZ\$365 per annum.

GEOGRAPHY—

PROFESSOR AND HEAD OF DEPARTMENT

The vacancy arises because of the retirement of Professor K. B. Cumberland in May 1978.

Besides being experienced in University teaching the applicants should be active in research and have a substantial record of research publications. Candidates suitably qualified in any branch of Geography will be considered.

At present professorial salaries are established within the range NZ\$19,748 to \$25,233 per annum having regard to the qualifications of the candidate concerned.

1027(A)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND

DEPARTMENT OF GEOLOGY

The Department of Geology invites applications for three faculty positions in *Sedimentology* and *Marine Geology* with special reference to the Labrador continental margin (subject to the availability of funds).

One appointment will be a regular faculty position at a salary and rank commensurate with qualifications and experience. The appointee will direct and participate in the activities of a research group working in the following specialties: Mesozoic and Cenozoic clastic sedimentology, clay mineralogy, sedimentary geochemistry and micropaleontology. Applications from suitably qualified candidates with working experience in the petroleum industry will be especially welcome.

Two appointments will be at the rank of Assistant Professor (Research) and will be for a two-year term in the first instance. Applicants should have proven research ability in one (or more) of the specialist fields listed above.

Applications for all three positions, which must include a detailed curriculum vitae and the names and addresses of three referees, should be sent by March 31, 1978, to: Dr David Skevington, Head, Department of Geology, Memorial University of Newfoundland, St John's, Newfoundland, Canada A1B 3X5.

1010(A)

Toxicologists

Continued site development has created openings for two experienced graduates to join our team evaluating the safety of novel therapeutic compounds and thereby assist in the development of new drugs.

In addition to a degree in an appropriate biological science, such as Pharmacology or Physiology, applicants should possess not less than two years' relevant practical experience. In return we offer a competitive salary and the fringe benefits associated with a major company. The Medical Research Centre is pleasantly located close to both London and Cambridge and unfurnished Development Corporation housing may be available at an economic rent.

Application forms (only) may be obtained by telephoning Harlow (0279) 419373. If you prefer, you may write, outlining your career-to-date, to:

John Atkinson, Site Personnel Manager, Beecham Pharmaceuticals, Medicinal Research Centre, The Pinnacles, Harlow, Essex, CM19 5AD.

Please quote reference: 9/N

977(A)

Beecham Pharmaceuticals

TECHNICIAN

with training in electron microscopy to join a laboratory working on biogenesis of membrane proteins. The job involves light and electron microscopy, autoradiography, immunocytochemistry and freeze etching. The post may be renewable for up to 3 years. Salary according to age and experience but not less than \$12,000 per annum.

Applications including curriculum vitae and addresses of at least two referees to Dr J. J. Kraehenbuhl, Institut de Biochimie, University of Lausanne, 1066 Epalinges, Switzerland.

958(A)

Institute of Cancer Research

TECHNICIAN

required to work on the mechanism of action of cytotoxic and carcinogenic compounds at Pollards Wood Research Station, Chalfont St. Giles, Bucks. H.N.C. or degree qualification required. Knowledge of sterile techniques and radioisotope labelling an advantage. Starting salary dependent on age and experience, not less than £2,964 p.a.

Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU quoting ref. 301/B/37.

981(A)

Ministry of Agriculture, Fisheries & Food, Pest Infestation Control Laboratory, Tolworth, Surrey.

Organic Chemist

■ Work on molecular basis of rodenticide action and resistance to anticoagulants
■ Synthesise novel organic chemical compounds
■ Study their interaction with biological systems in vivo/vitro.

□ Good honours degree or equivalent in appropriate scientific subject; final year students will not be considered
□ Experience of organic chemical synthesis essential
□ Interest in biological action of xenobiotics and a working knowledge of modern chromatographic techniques desirable
□ Age normally under 27
□ Appointment as Scientific Officer (£2870 - £4320) □ Ref: SB/34/AF.

■ Application forms (for return by 27 January 1978), from Civil Service Commission, Alencor Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke (0256) 68551 (answering service operates outside office hours).

1007(A)

Science Group
CIVIL SERVICE

free university amsterdam

The Department of Physics and Astrophysics has a vacancy for a

professor in (experimental) physics

An experimental physicist is required with experience in the field of intermediate energy physics and with interest in its theoretical aspects.

The person to be appointed is expected to cooperate with the present scientific staff of the Experimental Nuclear Physics Section in leading the current research of the laboratory, concentrated very much around the available AVF-cyclotron (maximal proton energy 30 MeV). He is, in particular, expected to contribute to a development of research in intermediate energy physics of this group to be conducted with the 500 MeV linear electron accelerator under construction at the I.K.O., Amsterdam.

To start a group of his own 2 or 3 positions are available. A gradual transition from the current job to the Free University can be arranged.

In due course he will have to take part in the education provided by the Department of Physics and Astrophysics, which will involve both lectures and the supervision of students undertaking research projects in the section.

The University hopes to find a candidate who can agree with the Christian aim and objective of the University.

Interested persons or those wishing to recommend another for the post should contact the secretary of the appointing committee, Prof. dr. H. Verheul, Natuurkundig Laboratorium der Vrije Universiteit, De Boelelaan 1081, Amsterdam - Buitenveldert, Phone: 020-584 24 69.

Applicants are requested to submit a curriculum vitae and a list of publications together with their application to Dienst Personeelszaken, De Boelelaan 1105, Post Office Box 7161, Amsterdam, not later than March 1, 1978 mentioning vacancy number 311-3045.

959(A)

M.R.C. NEUROCHEMICAL PHARMACOLOGY UNIT PEPTIDE CHEMIST

A temporary scientific staff position is available to develop work on the synthesis of analogues of peptides known to exist and act within the central nervous system, including the enkephalins and substance P. The person appointed will work closely with Unit staff involved in the assessment of the biological activity of such peptide analogues, and the chemical work will be undertaken with the supervision and guidance of Dr R. Shepard in the M.R.C. Laboratory of Molecular Biology nearby.

Candidates should ideally be aged 24-27 and have some previous training in peptide chemistry or a related subject to Ph.D. level or equivalent. The post is available for 3 years from April 1, 1978 or earlier.

Salary depending on age and experience in scale £3,975 to £5,219 M.R.C. conditions of service, including superannuation.

Applications in writing please to Dr L. Iversen, Director, M.R.C. Neurochemical Pharmacology Unit, Department of Pharmacology, Medical School, Hills Road, Cambridge CB2 2QD. Closing date for applications, February 17, 1978.

993(A)

TECHNICIAN

required in the Standards Laboratory for Serological Reagents. Suitable qualifications would include a relevant science degree, A.I.M.L.S., or H.N.C. in Medical Laboratory Sciences with experience in microbiology. The vacancy occurs in the unit concerned with the development and production of viral diagnostic reagents.

Salary according to age and experience, but not less than £2,184 per annum plus £354 London Weighting plus £454.50 Pay Supplements 1 and 2.

Applications with the name of at least two referees to Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. Tel. 205 7041. 966(A)

LOUGHBOROUGH UNIVERSITY OF TECHNOLOGY

Radiochemistry Research

Applications are invited for the post of S.R.C. RESEARCH ASSISTANT to participate in a project on radiolabelling drug molecules. Experience in radiochemistry or in biochemistry is desirable but not essential.

The appointment is for two years at a starting salary of £3,333 (under review). Application forms and further details from Dr David Malcolm-Lawes, Department of Chemistry, Loughborough Leicestershire 1014(A)

AN FORAS TALUNTAIS GRADUATE — MEAT INDUSTRY LIAISON OFFICER

AN FORAS TALUNTAIS invites applications for the above post in its Meat Research Department at Dunsinea Research Centre, Castleknock, Co. Dublin. The appointee will maintain technical liaison with the meat industry and will provide an information service on current research and development in meat science and technology.

ESSENTIAL: He/she will have an Honours University degree, or equivalent, as well as a food science or engineering background.

Experience in the food industry (preferably in the meat processing sector) will be an advantage. Commencing salary and level of appointment will depend on qualifications and experience. Non-contributory Pension Scheme with provision for Widows' and Orphans' pensions.

Application forms and further particulars from The Personnel Department, (Ref: MRD1), An Foras Taluntais, Headquarters, 19 Sandymount Ave., Dublin, 4. (Phone 01-688188). Latest date for receipt of completed forms Friday January 27, 1978. 963(A)

LINCOLN COLLEGE (University College of Agriculture) New Zealand LECTURER IN BIOCHEMISTRY

The Council of Lincoln College invites applications for the position of Lecturer in Biochemistry.

Applicants should have a degree in Science or Agricultural Science, and a postgraduate qualification. Preference will be given to those with experience in Agricultural Biochemistry. Duties will include teaching Biochemistry in the course for Bachelor of Agricultural Science, and the appointee will be expected to carry out research in Biochemistry related to Agriculture.

Commencing salary according to qualifications and experience within the range NZ\$10,239 to NZ\$12,543 per annum. At present salaries are supplemented by an "Interim Special Allowance" of 3.5%.

Travel and removal expenses reimbursed up to specified limits. New Zealand Government Superannuation available.

Conditions of Appointment are obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the College.

Applications close March 6, 1978. 982(A)

FACULTY OPENING IN BIOCHEMISTRY University of Illinois Champaign-Urbana

The Department of Biochemistry is seeking applicants for a tenure track appointment at the level of Assistant Professor or higher to begin August, 1978. Applicants should be qualified to teach biochemistry courses at undergraduate or graduate levels. Only candidates who have demonstrated excellence in research and who are prepared to establish an active research program will be considered, preference will be given to those who have received graduate and postdoctoral training in strong research environments. The minimum salary at the Assistant Professor level is \$15,000 for a nine-month appointment; salaries at higher ranks are negotiable. For full consideration, application materials, including a curriculum vitae, a list of publications, a brief description of research interests and three letters of reference should be sent by February 1, 1978 to:

Professor Lowell P. Hager, Head
Department of Biochemistry
University of Illinois
Urbana, Illinois 61801

Telephone: (277) 333-3945.
The University of Illinois is an Affirmative Action/Equal Opportunity Employer. 836(A)

The Daresbury Laboratory has a vacancy at Higher Scientific Officer level for research into the

THEORY OF ATOMIC AND MOLECULAR PROCESSES

The fields of interest of the Theory Group at Daresbury are atomic and molecular, solid state and nuclear.

At the Laboratory a major nuclear structure facility is under construction and work will soon begin on a purpose-built X-ray and ultraviolet source. An IBM 370/165 computer is installed at the Laboratory, and a computational science group has recently been established working mainly in the quantum chemistry area.

The appointment would be a permanent one at Higher Scientific Officer level made according to age, qualifications and experience in the range £3,245 to £4,454. There are also pay supplements of (a) £313.20 per annum and (b) 5% of total salary subject to a minimum of £130.50 per annum and a maximum of £208.80 per annum. There is a non-contributory superannuation scheme and a generous leave allowance.

Applicants, male or female, must possess a good degree in an appropriate subject plus two years relevant experience, and preferably a Ph.D. in the area of atomic and molecular theory or expect to obtain one in 1978.

Closing date: 21 February 1978.

Please write enclosing curriculum vitae, the addresses of two referees and quoting reference number DL/608/T to:

The Personnel Officer

DARESBURY LABORATORY
Science Research Council
Daresbury, Warrington WA4 4AD

975(A)

BIOCHEMISTRY FACULTY POSITION

The Biochemistry Department, University of California, Riverside, invites applications for an Assistant Professor position (tenure track) effective Summer, 1978. Although we have a slight preference for a person with a strong background in physical biochemistry who will initiate research into the structure and function of biologically interesting macromolecules and/or biological membranes, applications from outstanding individuals in other areas of biochemistry will receive serious consideration. The successful candidate will participate in the department's instructional program at the undergraduate and graduate level. Candidates should include in their application a statement of their current and future research objectives and a statement of their teaching experience and areas of competence. Send curriculum vitae, complete bibliography, duplicate copies of three representative publications, and the names and addresses of three references to: BIOCHEMISTRY SEARCH COMMITTEE, Department of Biochemistry, University of California, Riverside, CA 92521. Applications will be accepted until March 10, 1978 or until a suitable candidate is located. The University of California is an Equal Opportunity/Affirmative Action Employer. Minority and women candidates are encouraged to apply. 968(A)

POSTDOCTORAL POSITION (Research Associate)

available for 1 to 2 years beginning January 15, 1978 or February 1, 1978, to work on luminescences of DNA and related compounds. Involves working with pulsed frequency-doubled laser and digital data acquisition system. Experience with lasers and digital electronics advisable. Send curriculum vitae and names of three references to: Dr Malcolm Daniels, Chemistry Department, Oregon State University, Corvallis, OR 97331. Oregon State University is Equal Opportunity/Affirmative Action Employer and complies with Section 504 of the Rehabilitation Act of 1973. Closing date for applications is January 15, 1978. 967(A)

DEPARTMENT OF NUTRITION AND FOOD SCIENCE MASSACHUSETTS INSTITUTE OF TECHNOLOGY FACULTY POSITION

The Department, a large multidisciplinary teaching and research unit with activities in all principal areas of nutrition and food science is seeking an applicant to fill the following faculty position:

An M.D., with research training and preferably with a Ph.D. degree, and experience and a major interest in human and clinical nutrition. The appointee will be expected to teach graduate level courses concerned with human and clinical nutrition, to develop a vigorous research programme and become actively involved in the research programmes of the M.I.T. Clinical Research Center.

The appointment will be at the Assistant or Associate Professor rank depending upon the qualification of the successful applicant.

Curriculum vitae, together with representative publications and the names of five referees should be submitted before February 1, 1978 to: Dr V. R. Young, Chairman Search Committee, Room 56-331, Massachusetts Institute of Technology, Cambridge M.A. 02139, U.S.A.

M.I.T. is an Equal Opportunity Employer, Representatives of minority groups are urged to apply. 830(A)

CURATOR

THE GILBERT WHITE AND OATES MUSEUMS

seek full- or part-time Curator. Details: The Wakes, Selborne, Hampshire. 1029(A)

FACULTY POSITION IN BIOCHEMISTRY UNIVERSITY OF ILLINOIS AT URBANA CHAMPAIGN

The Department of Biochemistry is seeking applicants for a tenure track appointment at the level of assistant professor or higher to begin August 1978. Applicants should be qualified to teach biochemistry courses at undergraduate or graduate levels. Only candidates who have demonstrated excellence in research and who are prepared to establish an active research program will be considered, preference will be given to those who have received graduate and post-doctoral training in strong research environments. The minimum salary at the assistant professor level is \$15,000 for a nine-month appointment; salaries at higher ranks are negotiable. For full consideration, application material, including a curriculum vitae, and list of publications, a brief description of research interests and three letters of reference should be sent by February 1, 1978.

Professor Lowell P. Hager, Head
Dept. of Biochemistry
University of Illinois
Urbana, Illinois 61801
Telephone: (217) 333 3945
The University of Illinois is an affirmative action/equal opportunity employer. 785(A)

FELLOWSHIPS

IMPERIAL CANCER RESEARCH FUND DEPARTMENT OF CELLULAR CHEMOTHERAPY Research Fellowship

A postdoctoral cell biologist, biochemist or pharmacologist with previous experience or interest in *in vitro/in vivo* cloning techniques and/or cancer chemotherapy is required to join a group working on effects of antitumour drugs in normal and malignant cell systems, assessing the value of timing and sequencing of drugs in combination schedules, with particular emphasis on the design of safe combinations in terms of their effects on human bone marrow function.

Appointment will be for two years in the first instance with possible extension for a third year. Salary with entry according to qualifications and experience within range £4,649 to £5,669.

Further information from Dr Bridget T. Hill (tel: 01-242 0200 extn. 397). Applications with curriculum vitae and names of two referees, should be sent to The Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX by January 27, 1978. 978(E)

POSTDOCTORAL FELLOWSHIPS DEPARTMENT OF PHYSICS UNIVERSITY OF WATERLOO

Waterloo, Ontario, Canada

Applications are invited for post-doctoral research in physics

Fellowships carry a stipend of \$11,220 per annum. The awards are tenable for the period of one year with a possible renewal for a second year.

Research areas include:

Atomic and Molecular Physics, Biophysics, Brillouin Spectroscopy, Crystallography, Electron Microscopy, Electron tunneling, Ellipsometry, Experimental superconductivity, Diffraction Physics, Far-infrared spectroscopy, Infra-red and Raman Spectroscopy, De Haas-van Alphen effect, Laser Physics, Lattice dynamics, Magnetoconductivity of metals, Microwave Collision-Induced Absorption and Interferometry, Nuclear magnetic resonance, Semiconductors and amorphous semiconductors, Transport properties of gases and intermolecular potentials, Theoretical studies; magnetic impurities in superconductors, relativistic effects in metals, electronic structure in metals, nonlinear behaviour of elastic dielectrics, lattice dynamics of ionic crystals.

The applicants should submit their résumés and the names of three referees to:

Dr C. C. Lim
Department of Physics
University of Waterloo
Waterloo, Ontario, Canada
N2L 3G1 929(E)

SYMPOSIUM

MICROCOSMS IN ECOLOGICAL RESEARCH

November 8-11, 1978—Augusta, Georgia, U.S.A.

Savannah River Ecology Laboratory, in cooperation with University of Georgia's Institute of Ecology; U.S. Dept. of Energy; National Environmental Research Park program; U.S. E.P.A.'s Environmental Research Lab, Athens, Ga.; and, Electric Power Research Institute's Environmental Assessment Dept., will host ecological symposium on use of microcosms in ecological research. Symposium format will include presentations by invited speakers, panel discussions, and contributed papers. Abstracts due July 1; manuscripts due September 1, 1978. For registration and additional information contact: Dr John P. Giesy, Jr, Symposium, Savannah River Ecology Laboratory, Drawer E, Aiken, S.C. 29801, U.S.A. 1000(M)

AWARDS

THE WELLCOME TRUST 1 Park Square West, London NW1 4LJ Telephone: 01-486 4902 AWARDS FOR TROPICAL GASTROENTEROLOGICAL RESEARCH

The Wellcome Trust wishes to encourage research into major diseases of the gastrointestinal tract occurring in the tropics. Applications from gastroenterological or other appropriate departments will be considered. Preference will be given to proposals which demonstrate an interdisciplinary approach and especially those which include sustained collaboration with research centres in the tropics.

Competitive awards of up to £100,000 each are offered for a period of not more than five years. These awards are additional to the Trustees' normal arrangements for supporting tropical research.

Those wishing to apply should send a two-page summary of their objectives and proposals for research including a brief estimate of the anticipated costs for preliminary consideration. The summary should be accompanied by the curriculum vitae of the principal scientist involved. Applications should be addressed to Dr B. E. C. Hopwood, The Wellcome Trust, 1 Park Square West, London NW1 4LJ, and reach the Trust by March 21, 1978. 999(N)

RESEARCH FELLOWSHIP

Postdoctoral Fellowship in Human Cell Biology tenable for two years in the first instance with possible extension for a third year, available from January 1978 for studies on the regulation of DNA, RNA and protein synthesis and on the expression of breast specific function in primary cultures of human normal and dysplastic breast tissue. Candidates should be experienced in cell culture and in the biochemistry of growth regulation.

Salary with entry according to qualifications and experience within range £4,649 to £5,669.

Further information from Dr R. Hallows (tel. 01-242 0200 ext. 307). Applications with curriculum vitae and names of two referees, should be sent to The Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX by January 31, 1978 (Quoting ref. 33/78). 984(E)

DEPARTMENT OF MICROBIOLOGY DALHOUSIE UNIVERSITY HALIFAX, NOVA SCOTIA, CANADA

Applications are invited for POSTDOCTORAL FELLOWSHIPS to study viral pathogenesis with special emphasis on the role of interferon. Fellowships beginning July 1, 1978, are available for a period of two years with an initial stipend of \$12,720 per annum. Candidates should have research experience in the field of animal virology, preferably with an interest in the biochemistry of nucleic acid biosynthesis. Applications, consisting of curriculum vitae and names of two referees, should be sent no later than March 30, 1978 to Dr K. R. Rozee, Professor and Head, Department of Microbiology, Faculty of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada. 932(E)

MRC

Medical Research Council

Training Fellowships Scheme 1978-79

Tenable in the U.K.

The Council invites applications from suitably qualified candidates for MRC Training Fellowships.

Eligibility Requirements—

(candidates should have been ordinarily resident in the UK throughout the period of 3 years immediately preceding the application date)

(1) Graduates in medicine

(2) Graduates in dentistry

From post-registration up to Senior Registrar or equivalent at academic levels.

(3) Graduates in science

With PhD or D Phil, or with MSc plus at least 3 additional years' postgraduate experience; up to maximum seniority for a non-clinical academic lecturer.

Training Available

For (1), (2) and (3): specialised research training or training in the basic subject relevant to a particular clinical interest.

For (1) and (2) at House-Officer to Registrar or equivalent clinical academic level: a suitable MSc or comparable course.

Stipends

For (1), (2) and (3): appropriate point, with increments, on the current NHS medical (House Officer to Senior Registrar) equivalent dental, or current relevant academic scales.

Tenure

From 6 months to 3 years (or duration of MSc course).

Further information and application forms are available from: Medical Research Council, Training Awards Group, 20 Park Crescent, London W1N 4AL (tel. 01-636 5422 ex. 240).

CLOSING DATE FOR APPLICATIONS: 28 FEBRUARY 1978

Late applications cannot be considered.

986(E)

University of St Andrews Research Fellow in Statistical Computing

Applications are invited for a research fellowship to review and develop further statistical methods for exploratory data analysis. Postgraduate research experience is required, with a strong background in statistics. A working knowledge of computer methods and statistical software is essential.

The appointment will be for 2 years in the first instance, with the possibility of extension. Salary on Research Range 1A £3,333 to £5,627 plus U.S.S., starting point depending on qualifications and experience.

Applications (2 copies) including a curriculum vitae and the names of 3 referees should be sent by February 24 to Mr M. Weatherill, Department of Computational Science, University of St Andrews, Fife KY16 9SX, from whom further particulars may be obtained.

992(E)

UNIVERSITY OF MELBOURNE POSTDOCTORAL RESEARCH FELLOWSHIP in the DEPARTMENT OF MICROBIOLOGY

Applications are invited from Ph.D. graduates for the above-mentioned position which is funded by the Australian National Health and Medical Research Council and is available from January 1978 or soon after. The candidate will participate in a programme to develop continuous cell lines derived from immune lymphocytes. Previous experience in cytology, especially in the use of fusion hybrid techniques, would be an advantage. The position is available for two years with the possibility of renewal.

SALARY: \$A17,279 per annum. Enquiries will be welcomed by Dr W. Boyle, Department of Microbiology, University of Melbourne, Parkville, Victoria 3052, Australia. Applications referring to position number 526 355 should be addressed to The Registrar, University of Melbourne, Parkville, Victoria 3052.

1011(E)

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF CHEMISTRY POSTDOCTORAL RESEARCH FELLOWSHIP POSTGRADUATE RESEARCH ASSOCIATESHIP Molecular Dynamics of Photodissociation

Applications for two posts supported by S.R.C. are invited to undertake research in collaboration with Dr J. P. Simons. The experimental techniques to be employed include high resolution photo-fluorescence spectroscopy in the near and vacuum ultraviolet and time-of-flight photofragment spectroscopy using rare gas-fluoride ultra-violet laser sources.

The postgraduate position is tenable for three years and the holder will be encouraged to pursue research leading to a higher degree: the postdoctoral position is tenable for a maximum of two years: both can commence on or before October 1, 1978.

Salaries: Fellowship on the scale £3,333 to £5,627, (under review), plus superannuation. Maximum starting salary £3,761.

Associatehip on the scale £2,904 to £4,190 (under review), plus superannuation. Maximum starting salary £2,904.

Further particulars from the Assistant Registrar, (Science and Engineering), University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (three copies) with full c.v. and naming three referees should be sent by Friday, February 24, 1978. Please quote ref: NF4.

971(E)

COURSES

FLOW LABORATORIES PLANT TISSUE CULTURE COURSE

to be held in Edinburgh, April 3 to 7, 1978. The Course will be run by Dr M. M. Yeoman and will consist of lectures, experiments and demonstrations of the techniques involved in the preparation of explants, the production and sub-culture of callus cultures, organ culture, protoplast production and culture, and the induction of organogenesis.

The fee for the Course will be £135 plus VAT inclusive of accommodation.

Application forms are available from Dr S. A. S. Volkers, Flow Laboratories Ltd., P.O.B. 17, Second Avenue, Industrial Estate, Irvine, KA12 8NB, Ayrshire.

1023(D)

UNIVERSITY OF SALFORD DEPARTMENT OF BIOLOGY Applications are invited for a Science Research Council RESEARCH ASSISTANTSHIP

to work with Dr V. W. Pentreath on nerve/glia relationships in invertebrate nervous systems. The appointment, of three years duration, will be made up to Postdoctoral (Grade 1A) level. Applicants should preferably have experience with electron microscopy and/or autoradiography.

Applications with curriculum vitae and two academic references should be sent to the Registrar, University of Salford, Salford M5 4WT, by January 31, 1978, quoting Reference B/72/N.

1022(P)

IMPERIAL COLLEGE OF SCIENCE & TECHNOLOGY ROYAL DUTCH SHELL SCHOLARSHIP IN GEOLOGY OR GEOPHYSICS 1978-1979

Normally of equivalent value to a N.E.R.C. Postgraduate Studentship plus supplementation, plus college fee and approved fieldwork expenses. Tenable for up to three years of research in a topic which falls within Shell's general field of interest. Candidates must have taken, or be taking in the year of award, either an honours degree in Geology, preferably with mathematics and/or Physics at an ancillary level, or an honours degree in Physics. Candidates should be no more than 27 years of age, and medically fit to work abroad.

Applications, on a special form obtainable from the Registrar, Imperial College, London SW7 2AZ must be received by April 14, 1978.

694(H)

The Macaulay Institute for Soil Research, Aberdeen

RESEARCH STUDENTSHIPS

Applications are invited from students who hold or expect to hold upper second class honours degrees in the appropriate subject for Ph.D. studentships at the standard S.R.C./A.R.C. rates for work in the following areas:

Spectroscopy (E.S.R. and Laser)
Physical Chemistry (Sorption and Thermochemistry)
Organic Chemistry (Enzymes)
Plant Physiology (Calcium translocation)

Candidates, who must have British nationality, should submit applications to Professor T. S. West (Director), The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen AB9 2QJ.

987(F)

CONFERENCES

ELECTROPHORESIS '78

An international conference and poster presentations will be held at the MIT Krege Auditorium in Cambridge, Massachusetts, April 19-21, 1978. More than twenty invited speakers will present lectures on all types of electrophoretic and isoelectric focusing methods and applications to proteins, nucleic acid and cell separation. Abstracts for poster presentations must be received by March 1, 1978. Pre-registration is required. For brochure and registration forms write to:

Prof. Nicholas Catsimopoulos
MIT, Room 56-307
Cambridge, Massachusetts 02139

Photomacrography: easier than ever before.

WILD M400 PHOTOMAKROSKOP.

No other photographic technique today is so reminiscent of the methods of yesteryear's pioneers in photography as is photomacrography (range 1:1 to 20:1). In the past, the bellows was unwieldy, setting the image scale complicated and calculating the exposure time a long-drawn-out operation. You literally had to grope for the object. Not what you would call efficient! And yet efficiency is just what is needed in science and technology where photomacrography is playing an ever more important role.

Now Wild Heerbrugg has developed a new photomacrographic system, the Wild M400 Photomakroskop.

Modern photographic technology and electronics guarantee a high degree of efficiency within the magnification range of 1:1 to 60:1. Magnification and detail can be continuously varied with the macrozoom objective 1:5. What's more: the M400 gives you binocular observation under **optimum physiological conditions**, an erect and laterally-correct image and a great working distance. The specimen remains in focus over the whole zoom range. The electronic control unit ensures **ideal exposure time at the touch of a button**, independently of camera format, film emulsion and illumination method. It's easier and better than ever before.

Wild Heerbrugg Ltd.

Chemistry of Gondwanaland's lithosphere

ARE YOU CONCERNED WITH THE QUALITY OF ENZYME-LABELLED ANTIBODIES?

**At the PASTEUR INSTITUTE,
we use for coupling only pure antibodies isolated by
affinity chromatography, and pure enzymes
of the highest specific activity.**

PURITY GUARANTEES QUALITY

**We are glad to offer the following products for your research
or clinical experimentation in the field of immunochemistry,
enzyme-immunocytochemistry, enzyme-immunoassay:**

Peroxidase labelled:

- Antibodies or Fab anti-human IgG (H + L)
- Antibodies or Fab anti-rabbit IgG (H + L)
- Antibodies or Fab anti-mouse IgG (H + L)
- Antibodies anti-sheep IgG (H + L)
- Antibodies anti-goat IgG (H + L)
- Antibodies anti-human IgA (specific α)
- Antibodies anti-human IgG (specific γ)
- Antibodies anti-human IgM (specific μ)

Also available on request:

- Antibodies or Fab coupled with glucose-oxidase, alkaline phosphatase, β -galactosidase.

New liquid scintillation review

Sample preparation in liquid scintillation counting
by C.T. Peng.

A recent title in our series of Review Booklets on
subjects of interest to users of radioisotopes.
It includes a brief account of liquid scintillation
processes, and a review of the various aspects of
sample preparation.

The booklet will bring the most pertinent information
on sample preparation to new users and more recent
developments to those already familiar with the
technique.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Systeme International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

Cytotoxic T cells learn specificity for self H-2 during differentiation in the thymus	R. M. Zinkernagel, G. N. Callahan, J. Klein and G. Dennert	251

How Britain runs its science

This highly successful chart, which appeared in Nature 28 August 1975 (but is still much requested and much referred to), has now been completely revised and updated to include all major changes in the personnel and administration of British science.

Measuring approximately 2' x 3' and containing black-and-white illustrations of prominent figures, copies of this chart are now available at 75p (UK), US \$1.50 (Rest of World).

Payment may be made in any currency at the prevailing exchange rate. Cheques should be made payable to Macmillan Journals Ltd. Prices include postage and packing.

To order please complete the coupon below, or write, enclosing the correct remittance.

Cinderella in the UN

MANY of those in touch with the preparations for the UN Conference on Science and Technology for Development (UNCSTD), now scheduled for Vienna in August 1979, have been concerned with the apparently low priority given to possible contributions from the world scientific community. Recently, however, there would seem to have been a change of heart, if not within the UN's own Office of Science and Technology, at least on the part of Mr da Costa, the Conference's Secretary General.

This much became apparent at the meeting in Geneva last November of the Advisory Committee on the Applications of Science and Technology, ACAST, the United Nations' informal committee. ACAST was one of the few concrete results of the last big general conference on the Application of Science and Technology for the Benefit of Less-developed Areas (UNCSAT) held in 1963. Rather to the surprise of ACAST's members, who had previously found him somewhat inclined to play down the part that scientists might play in 1979, da Costa went to some pains to stress the important contribution they could and should make not only at the Conference itself, but also in the preparation of the national papers that will provide the principal input to UNCSTD. He spoke, too, of the "necessity to ensure the participation of scientists at the forthcoming session of the UNCSTD Preparatory Committee", which "will allow them to speak alongside diplomats at a very early stage in the Conference preparations".

In fact, competition for the floor of meetings is less likely to be between scientists and diplomats than between scientists and 'experts' in the development business who represent, in UN terms, the UNCTAD and UNIDO lobbies.

The UN is still agonising about whether it should have a science and technology policy at all. This is the subject of an important report from ACAST that will be considered by the Committee on Science and Technology for Development (CSTD—the secretariat of UNCSTD) at its meeting which starts on 23 January in Geneva. While ACAST itself believes that "there is a need for a policy which would guide and facilitate the development and application of science and technology by and within the United Nations system for the benefit of its Member States" the various members of the UN family, and in particular the specialised agencies, seem

decidedly lukewarm if not frankly antagonistic to this idea. The fact is that, although themselves almost without exception based to a greater or less extent on science or its immediate applications, they are notoriously jealous of their own sovereignty in matters of policy—indeed, it sometimes seems that this is almost the only thing on which they can agree.

Nonetheless, if the agencies which purport to advise and assist the developing countries in applying science and technology cannot agree at least to certain priorities in this field, much of their effort will be wasted and the developing countries themselves will still lack the guidance they so desperately need on where to go and how to set about getting there. In this context, the new report from ACAST is well worth careful study and consideration, as much outside the UN system as within.

As to ACAST itself, after a period when, again within the UN system, its very usefulness has been called in question, the recent meeting should have dispelled any doubts as to its value. Its members do not sit as official government representatives but in their own right as scientists of international repute, and covering a very wide range of disciplines. This also seems to have been recognised by Mr da Costa when he stressed the value of ACAST's role in "acting as a bridge between the Conference Secretariat and the scientific community" particularly with regard to the participation in 1979 of the major non-governmental organisations such as ICSU, the Pugwash Conference and the World Federation of Engineering Organisations (WFEO), all of whom found it worthwhile to send observers to the ACAST meeting.

One point which may be of concern to British scientists is that at present no scientists from this country is a member of ACAST. This is partly because in inviting scientists to sit on this Committee, the UN Secretary General seeks to avoid the impression of any permanent 'national' representation. In part, too, even ACAST is affected by the move to include more representation of the developing countries among its members (in fact the Chairman of the recent meeting was Dr Chagula of Tanzania). Be that as it may, there is little doubt that when, as will surely happen sooner or later, there is any suggestion that a British scientist should once again be invited to sit on this, the only UN body that can speak for science and scientists, it should be warmly welcomed. □

Is British physical anthropology dying?

Bernard Campbell, Adjunct Professor of Anthropology, University of California, Los Angeles, argues that teaching and research in physical anthropology should be developed and expanded in the UK.

RESEARCH and teaching in the most fundamental branch of the science of physical anthropology is today almost extinct in Great Britain. Senior positions are no longer available, and almost all the talented scholars in the field have moved to the US or Canada. Human palaeontology, as a key part of the anthropological sciences, is taught by permanent staff in the Anthropology Department of only one University: Cambridge. While it is also taught in a limited way in at least five anatomy departments of medical schools, this teaching is generally in the context of human anatomical studies and is therefore not in its most appropriate milieu, namely, the knowledge of human society and culture, and of the evolutionary paradigm.

This is a near disaster. Physical anthropology, concerned as it is with man's biology, is the study of the most fundamental aspects of human nature. While it can be said to date from J. F. Blumenbach (1752-1840) (who classified races and made a collection of human skulls) it came of age and gained its central paradigm with the publication of Darwin's *Origin of Species* (1859).

Today, physical or biological anthropologists study Man as a product of natural selection and try to understand human variability in the light of evolution. The biology of Man has branched into many sub-disciplines, including comparative anatomy and comparative physiology, which are at the centre of human biology; the study of human growth and variability; genetics; primate palaeontology; primate behaviour; human ecology; and many others. Physical anthropology is therefore necessarily disparate in its specialisations.

At University College, London, for example, staff are presently doing research into the systematics of the *Galagidae*, the genetics of marriage in modern Britain, the serological genetics and nutrition of Carib populations, the genetics of Ethiopian baboons, and the strength and structure of bone. Many of these specialisations lean heavily on developments in related sciences, especially human genetics and physiology, and zoology. Sometimes it seems that these diverse specialists would be better placed in other departments. Yet research into human blood-groups was immensely stimulated by anthropological considerations and data, and studies of primate behaviour were given a new focus by anthropologists S. L. Washburn and I. DeVore. Anthropologists have both received from, and given to, related disciplines, and their central interest in 'the proper study of mankind' energises and directs their research.

In the early years of this century Karl Pearson, G. M. Morant and others, worked painstakingly with calipers and measuring tapes to produce a vast amount of quantitative data about the skeleton of modern man. They also studied the rather limited fossil record in the same way. The method produced meagre results and in the 1940s Fisher's population genetics and the new research on the ABO blood groups developed as a far more powerful tool with which the nature of racial differences and at least recent human prehistory might be uncovered. The dimension of time proved elusive, however, and while the genetical aspects of Man's place in nature probably hold pride of place today in most departments of physical anthropology throughout the world, these studies do not and cannot develop that central explanatory paradigm, which alone can hold physical anthropology together as a science.

The fossil evidence for human evolution and its interpre-

tation into a more complete understanding of Man's past has become alive again with the development of a functional approach to anatomical analysis. S. L. Washburn was probably the first to insist on its importance (circa 1950) and others followed. My book *Human Evolution* (1966) was an early attempt to make such a functional integration. The bones came to life, and behavioural speculation followed. As a result physical anthropology came closer to its sister discipline, prehistoric archaeology: together they constitute the science of evolutionary anthropology or palaeoanthropology *sensu lato*. Palaeoanthropologists are not today expected to be outstanding scholars in both human palaeontology and prehistoric archaeology, but they are expected to be very much aware of the value of each science and its vital importance in understanding the evolution of human nature. The interdisciplinary study of the evolution of man which also includes vertebrate palaeontology, palaeoecology, and palaeogeography, is necessarily the main stem from which all the sub-disciplines of physical anthropology mentioned above are nourished. In spite of the complexity of anthropology, an anthropologist must necessarily be a generalist as well as a specialist: he must specialise in the light of his knowledge of mankind's whole adaptive strategy.

Human palaeontologists must, therefore, more than ever before, rub shoulders with social and cultural anthropologists and archaeologists: and at the same time they must see man at all times—not as a creature apart from nature, but as a very remarkable animal. It follows that although the anatomy departments have housed and nourished human palaeontologists for three to four generations in the UK (since the time of Sir Grafton Elliot Smith and Sir Arthur Keith), they can no longer remain the primary resource for this subject.

At a recent inaugural meeting in London, the L. S. B. Leakey Foundation presented its goal of further study into "Man's origin, behaviour and survival", and plans to support students and research projects in areas which reflect this holistic approach to the study of man. What is needed in Britain is a Department of Physical Anthropology with the prestige, money and manpower to bring back to Britain some of those palaeoanthropologists who have left. Britain needs a university with the will and the resources to bring to life the main stem of all anthropology—the study of human evolution. Man has been part of Nature—as a hunter and gatherer—for 99% of the approximately 2 million years of his existence on earth. Man is a product of his prehistory, and our understanding of our present predicament depends squarely on our knowledge of our own past. □

"Of course, they're extinct now too!"

Research with prisoners

After 18 months' deliberation the US Secretary of Health has responded to a report questioning the ethics of research involving prisoners. **Michael S. Yesley** and **Barbara Mishkin**, closely involved in the production of the report, here discuss their findings

UNDER American law new drugs must undergo three phases of testing before being approved by the Food and Drug Administration (FDA) for general sale. Phase 1 involves the first introduction of a drug in humans and requires testing on normal volunteers to determine the safety and general metabolic properties of the drug. Phase 2 consists of controlled clinical studies on a small number of patients to determine therapeutic efficacy. (In the United Kingdom and elsewhere, phases 1 and 2 are consolidated by testing for safety as well as efficacy on a small number of patients for whose treatment the drug is intended.) Phase 3 is similar to phase 2 but involves considerably more patients. Although no data are available by which to ascertain the extent of the use of prisoners in phase 1 tests in the United States, it is clear that they are used to a significant degree.

The reasons for the practice are partly historical. During the Second World War, civil prisoners in Illinois and New Jersey participated in research to develop treatment for malaria and other diseases that afflicted the armed forces. Such participation was considered not only acceptable but praiseworthy, for it gave inmates an opportunity to contribute to society (a form of restitution) and to enhance the war effort. Following the war, the involvement of prisoners in non-therapeutic biomedical research increased as a result of expanding government support for biomedical research and more stringent federal requirements for evaluating the safety of new drugs.

At the same time that the use of prisoners was increasing in the United States, the world was reacting to revelations of the experiments conducted in the Nazi prison camps. The Public Health Council of the Netherlands, for example, responded by specifically disapproving research involving children, old people, the insane and prisoners. The Nuremberg Code, initially drafted by an American consultant to the war crimes tribunal, is somewhat ambiguous with regard to the involvement of prisoners in research. The first principle of the Code provides that: "The voluntary consent of the human subject is essential. This means that the person involved should have legal capacity to give consent: should be so situated as

Self-confidence training at Wisconsin State Reformatory

to be able to exercise free power of choice without the intervention of any element of force, fraud, deceit, duress, overreaching, or other ulterior form of constraint or coercion. . . ."

Many have interpreted this provision to mean that civil prisoners may not participate as research subjects, because they are not "so situated as to be able to exercise free power of choice." In the United States, however, it has been argued by the research community and by some prisoners themselves that so long as the prisoners are fully informed and no obvious duress is imposed, they may be considered free volunteers. This assertion is at the centre of the recent controversy in the United States over the participation of prisoners in research.

Jessica Mitford's book *Kind and*

Usual Punishment, published in 1973, was partly responsible for calling the public's attention to this issue. Mitford perceived drug research to be an exploitation precipitated by FDA drug-testing requirements and perpetuated by the economic self-interest of drug firms, investigators, prison authorities and the inmates themselves. Concurrently, academicians and civil rights organisations began to question the validity of any consent given by prisoners to participate in nontherapeutic research. They suggested that voluntary consent was impossible in penal institutions because of the poor living conditions, fear of physical violence in the cell-block, absence of good medical care and alternative ways to earn money in prison, and the obvious advantages, therefore, of leaving the general prison quarters to be paid for living in a research unit with access to individuals from the outside world. They also suggested that in a closed society such as a prison, the opportunity for exploitation is especially great when, as Mitford pointed out, prisoners are frequently prevented from reporting abuses to those on the outside.

Proponents of prison research have argued, on the other hand, that if research in prisons were to be prohibited, the result would be an inability to assure the safety of new pharmaceuticals, since prisoners are most likely to have the time and inclination to subject themselves to the kind of tests required by FDA to establish safety of new drugs. The proponents state, in addition, that phase 1 drug testing presents little risk, that injuries have been few, and that procedures are available to assure that consent is freely and knowledgeably given without undue influence or coercion.

In the midst of this debate, the National Commission for the Protection of Human Subjects of Biomedical and Behavioural Research was established by Congress to conduct studies and make recommendations in several areas of controversy involving

Drs Yesley and Mishkin are Staff Director and Assistant Staff Director, National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, Washington, D.C., but the views expressed herein are those of the authors and do not necessarily reflect those of the Commission.

human subjects, including the participation of prisoners. The Commission set out in 1975 to investigate the validity of the various claims put forth and to examine the legal and ethical issues surrounding the participation of prisoners in research. The members of the Commission and its staff visited several prisons where research is conducted and interviewed over 250 prisoners who participate in research. The Commission conducted public hearings at which arguments for and against prison research were presented, and sponsored a conference at which the view points of minority populations were expressed. In addition, several papers and studies were prepared for the Commission on topics including the nature and extent of prisoner involvement in research in U.S. prisons; alternatives to the use of prisoners and foreign practices in drug testing; philosophical, legal and sociological perspectives on the involvement of prisoners in research; experimental behavioural practices involving prisoners; and a sociological study of research at five prisons.

The Commission found that virtually all prisoners participating in biomedical research feel that they do so freely and do not want to lose this opportunity. Most prisoners who were interviewed candidly cited financial reward as the main reason for their participation in research, and they did not appear to be motivated by the expectations of early release (which, in fact, is not granted for research participation). Further, data indicate that even in prisons where the inmate population is predominantly black, the research subjects are predominantly white, and they tend to be better educated and to hold better prison jobs than the nonparticipants. This finding contradicts the general belief that prison research exploits minority groups and those unable to obtain good prison jobs (to the extent such employment is available).

The Commission was impressed with reports of programmes that successfully use nonprisoner volunteers in phase I drug testing. At least one principal investigator (who formerly used prisoners for such research) reported that nonprisoner volunteers are preferable for scientific as well as social and ethical reasons. It is easier to control the subjects' abuse of drugs, for example, in a well-run research facility than in a prison. Further, he reported, the subjects become experienced in the bargaining and consent process, they are knowledgeable about the responsibilities and risks they are undertaking, and it is possible to provide commercial insurance to compensate them for any injuries that might occur.

With respect to the risks of phase I

Learning to concentrate by crawling

drug testing, it appears that they are not significant. One commercial company that provides insurance for non-prison volunteers has estimated that the risk of such "employment" is roughly equivalent to that of being a secretary.

This situation, in which the prisoners expressed their desire to participate in research, while advocates and other outside observers argued that the prisoners were unduly influenced, posed a dilemma for the members of the Commission. The irony was not lost that recognition of the limited options in prison life might be used to justify the removal of one of those options. On the other hand, it is likely that many prisoners who participate in research would choose not to do so if the conditions of prison life were substantially improved or there were optional sources of equivalent income. This likelihood may indicate undue influence, and thus involvement of prisoners in research may well constitute an exploitation.

Despite the confidence of prisoners that their participation in research was entirely voluntary, the Commissioners expressed doubts that conditions generally prevalent in United States prisons provide a setting in which voluntariness can be relied upon. The Commissioners also expressed reservations about the

conduct of research in institutions that are isolated from public scrutiny and in which access to the outside is limited. The Commission concluded that the conduct of nontherapeutic research should be permitted only under acceptable prison conditions and that the burden of proof as to the social necessity of using prisoners as subjects in nontherapeutic research should be on those who wish to continue the practice.

The Commission therefore recommended to the Secretary of Health, Education, and Welfare and to Congress that the participation of prisoners in nontherapeutic research not be permitted unless any prison proposed as a site for such research is able to meet a long list of specific standards regarding health and safety conditions, job opportunities, free communication with persons on the outside, prisoner representation on research review boards, and the right of prisoners to form effective grievance committees. In addition, any investigator proposing to use prisoners in such a facility must demonstrate that the need to use prisoners in a particular research project is compelling and that such use would not result in social inequity.

The Commission recommended, however, that research designed to improve understanding about the causes of deviant behaviour, the effects of incarceration, and the factors related to parole performance and recidivism be permitted, so long as certain procedures are followed to protect the rights of prisoners, to safeguard their privacy and to preserve the confidentiality of the data obtained.

The Commission's recommendations* were submitted to the Secretary of Health, Education and Welfare in October 1976. After a delay occasioned by disagreement in the department over the wisdom of implementing the recommendations, Secretary Joseph Califano, Jr., announced last month that he would issue regulations even stricter than those recommended by the Commission for nontherapeutic research with more than minimal risk (e.g., phase I drug testing). In fact, he proposed to ban the participation of prisoners in such research under any conditions. The Secretary's stated grounds for his decision espoused the arguments of civil rights advocates that prisoners, by the nature of their situation, are incapable of giving informed consent. □

*Copies of the Commission's report and recommendations may be obtained by writing to: Public Information Officer, National Commission for the Protection of Human Subjects, Room 125, 5333 Westbard Avenue, Bethesda, Maryland 20016.

Fermilab's director threatens resignation

FOR a considerable number of years, Europe's high energy physicists have looked enviously at the facilities and resources available to their US colleagues. Recently, however, the pendulum has begun to swing the other way; American physicists, faced with rising costs and conflicting demands on a limited budget, now speak of the need to "keep up with the Europeans".

The most dramatic manifestation of this has been the suggestion by Dr Robert R. Wilson, director of the Fermi National Accelerator Laboratory near Chicago, that he will resign his post next month unless the Government provides sufficient funds for early completion of the laboratory's proposed 'energy doubler', a development which would both cut down running costs and allow the laboratory to reach energies of 100 GeV or more.

Wilson stated his position in a letter to Mr James R. Schlesinger, Secretary for Energy, whose department is responsible for high energy physics laboratories. Schlesinger's proposed budget for 1979 will be presented to Congress next week by President Carter. And although regarded by some as an attempt at special pleading, Wilson's move has highlighted tensions over the allocation of funds within the high energy physics community.

Fermilab—the "jewel in our crown" as one member of this community puts it—was completed on time and within budget (\$340 million) in 1972. Although designed to carry out experiments at 200 GeV, it has been operating at energies of up to 500 GeV, and was for several years the most powerful particle accelerator in the world. Much important and exciting physics has come out of the laboratory. Only last year, for example, Fermilab announced the dis-

covery of the new ψ particle of mass about 10 GeV. This particle is believed to be similar to the J/ψ at 3.1 GeV and to herald the presence of a new quark.

Yet it has been estimated that the new SPS proton synchrotron facility at the European Centre for Nuclear Research (CERN) in Geneva, which came into operation at the beginning of last year and currently operates at about the same energy at Fermilab, enjoys almost twice the level of support from research teams financed by the different European countries involved. As a recent article in the Fermilab house journal put it "whereas we welcome the arrival of our friends and co-investigators in the field of 400-GeV physics, we also must be mindful of the competition. There is no point in doing an experiment at Fermilab, quite similar to one being done at CERN, and doing it less well."

"At present, we are doing only about half the amount of physics a year that we could be doing" according to Dr Edwin L. Goldwasser, deputy director of the laboratory. "And in two or three years time, if there is no improvement in funding, we could find ourselves in a relatively weak position internationally." Already it is planned that Fermilab's meson facility is to close for six months for lack of funds.

Saving energy—and thus reducing Fermilab's \$5 million electricity bill—is therefore one of the attractions of the "doubler" project, under which a second ring of superconducting magnets would be constructed using the same tunnel as the existing ring.

According to Dr Goldwasser, a whole new set of experiments would be opened up by such a facility, which would be able to provide proton energies on a target of up to 1000 GeV (43 GeV in the centre of mass). And by circulating particles in opposite directions in the two rings—for example protons and antiprotons—collision energies of 2000 GeV in the centre of mass, at high luminosity, could be reached.

With the major part of the development work carried out, Wilson is now keen to move forward rapidly to the construction phase. "At present the doubler would cost between \$30 and \$35 million, and given this money—which would mean a total budget for the laboratory of about \$120 million in 1979—we believe that the doubler could be completed by the end of 1979" says Dr Goldwasser.

Members of the Department of Energy's High Energy Physics Advisory

Panel, who would recommend the funding, are sympathetic to Wilson's position. There is a widespread feeling that, despite new facilities and continuously increasing budgets, the overall position of high energy physics is precarious. According to Professor Sidney Drell, for example, who is chairman of HEPAP and deputy director of the Stanford Linear Accelerator Center (SLAC) in California, the present level of funding is "perilously low", with virtually all major equipment being underutilised.

In this climate, there is a natural concern that Fermilab should continue to operate effectively and competitively. And HEPAP has suggested that, for the time being at least, the administration should hedge its bets and continue to support all its major accelerator facilities. But the question has become one of deciding relative priorities.

In particular HEPAP has been faced with the choice between upgrading Fermilab's facilities by constructing the "doubler" as Wilson suggests, and providing support for a new facility, the 400 GeV intersecting proton beams project (Isabelle) at the Brookhaven National Laboratory on New York's Long Island.

At present, while emphasising that it is "strongly committed" to both projects, HEPAP's vote for top priority has gone to Isabelle, just as five years ago it recommended that funds for other areas of high energy physics be held back to allow Fermilab to be developed.

HEPAP's position was confirmed at a meeting of the panel attended by both Wilson and Goldwasser in early December (and planned, ironically, to coincide with the opening of a new gallery devoted to particle accelerators in the Smithsonian's Museum of History and Technology, with Fermilab as one of the centre-pieces).

This position is likely to be reflected in the proposed science budget for 1979 which President Carter will offer to Congress next week. In this it seems likely that a major sum will be allocated for Isabelle under the Department of Energy's construction programme, but that the sum earmarked for Fermilab's energy doubler will not be large, and will come from the laboratory's operating budget.

Wilson reaches retirement age next year, and would naturally like to see the doubler well under way—if not finished—before he goes. If the administration's proposed budget does not provide the money for him to do it, then his last chance would rest with the appropriation and authorisation committees in Congress which could— if so persuaded—add an additional earmarked sum.

David Dickson

Mediterranean pollution: one man's optimism

THE 1978 Monaco meeting of the 17 Mediterranean countries involved in the 'Mediterranean Action Plan' to clean up pollution closed last Saturday to such headlines as 'Deadlock over Med' and 'Pollution talks go into stagnation'. But in Geneva, the headquarters of the United Nations Environment Project's 'Regional Seas' programme, one man remains unrepentantly optimistic: the director of the programme, and inspiration of the Mediterranean Action Plan, Dr Stjepan Keckes.

Dr Keckes (his name is pronounced 'Keshkesh') is almost literally the power behind the Mediterranean plan. A 46-year-old marine scientist, member of the Hungarian minority of Yugoslavia, he has in 4 years established a ring of 79 cooperating research centres (some of them in perpetually antagonistic states such as Greece and Turkey, Egypt and Israel) and produced a baseline study of Mediterranean pollution which all governments respect—no mean achievement.

And with his principal colleagues Patricia Bliss (legal adviser) and Mohammed Tangi (environmental management) Keckes has been responsible for a sequence of inter-governmental agreements on pollution which, despite Monaco, has been one of the jewels in the UN's crown. Next month the first of two protocols to control dumping and environmental accidents come into force, ratified by six Mediterranean states (Spain, France, Yugoslavia, Tunisia, Lebanon and Monaco). Few international agreements move so fast: only 10% of the signatories to the 1973 London Dumping Convention, for

example, have ratified the Convention. Keckes can claim 33% in two years for the protocols of the 1976 Barcelona Convention on Mediterranean pollution. Keckes has a right to be optimistic.

Speaking this week from Geneva Keckes told *Nature* that he was "perfectly satisfied" with the meeting in Monaco, and that it had "fulfilled our expectations completely". That cannot be entirely accurate, however, for Keckes, interviewed by *Nature* in December, spoke of the Monaco meeting paving the way for the adoption of a third protocol—the one that bites, on land-based sources, which deliver 80% of the pollution load—"by the autumn" of 1978. At Monaco, however, there was little progress on the protocol and a further discussion session has been planned for Geneva in October—to be followed by a meeting in Athens to adopt the protocol at no specified date. Keckes, ever optimistic, is delighted that at least the place for the adoption of the protocol—Athens—has been decided.

The third protocol defines a 'black list' of substances that must on no account be released to the Mediterranean, and a 'grey list' which can be released but only in certain limited amounts. The governments involved have estimated that to implement the necessary controls would cost some \$10 billion in initial capital investment, a large part of it to control the industrial pollution flowing from the rivers Rhone (France) and Po (Italy). Difficulties have arisen over the North-South dialogue, with Southern Mediterranean states fearing that the con-

trols will inhibit their industrial development; and over whether the countries responsible for most of the pollution should pay compensation to the other states; and over the control of pollution in rivers.

Keckes remains satisfied that these difficulties will be solved, while recognising that agreeing the third protocol will be "the most difficult thing Mediterranean states will ever negotiate. We are not rushing them".

There were successes at Monaco. The most significant scientifically is the agreement to set up a study of, and consider a protocol on, air pollution over the Mediterranean. Air pollution will be "one of the biggest surprises in the future" Keckes believes. Much of the mercury and lead pollution arriving in the Mediterranean may travel first through the air, not water. And Keckes can now begin setting up some 10 to 15 new laboratories to monitor the air transport of pollutants. He expects results in 4 to 5 years. Another Monaco success for Keckes is his successful resistance of moves to make the pollution research reports secret. Keckes insisted they will be published; and they will be.

Keckes has ensured that governments approve their own research stations, so their results cannot be dismissed; and has insisted that the research be done by them rather than for them, to build up a national base for pollution monitoring. (UNEP has provided \$1.7 million for this purpose.) He has made sure that all results are intercalibrated, to be strictly comparable. And no doubt to the comfort of the least developed nations of the Mediterranean he also argues that for UNEP "protection of the environment is just one dimension of the development of the environment—for us protection for its own sake doesn't exist."

Stjepan Keckes: Confronting governments with reality

Rogers suggests interim legislation on DNA research

THE draft of a new bill covering both public and private research on recombinant DNA has been produced by Representative Paul G. Rogers in an attempt to break the deadlock on congressional legislation that developed late last autumn.

According to the provisions of the proposed bill, interim legislation would come into effect for a period of two years under which all such research would be required to be covered by guidelines laid down by the National Institutes of Health.

In addition, a commission for the study of research and technology would be set up charged with conducting a study of federal policy regarding activities involving the genetic modification of organisms and viruses. The commission would make a report within two years containing recommendations regarding federal action to be taken to promote, regulate or review such activities.

Mr Rogers is chairman of the sub-committee on health and the environment of the House Committee on Interstate and Foreign Commerce. Discussion on an earlier bill supported by the sub-committee was not completed by the full committee in the last legislative session, and the delay meant that the bill did not reach the floor of the house.

Under the provisions of the new bill, all those in the process of carrying out experiments involving recombinant DNA or proposing to do so would be required to provide an assurance to the secretary of the Department of Health, Education and Welfare that the work was being carried out in accordance with the NIH guidelines (the present guidelines, which were introduced in 1976, are currently being revised).

Those found to be ignoring the guidelines would be liable to a civil penalty (a fine) and the possible suspension of research funds.

Supporters of the new bill are hoping that by avoiding some of the more controversial aspects of the present debate—such as the problem of the 'prior disclosure' of research results, or the legal protection of employees who provide evidence of infringements—it will bring together house, senate and administration thinking, and have a higher chance of success than last autumn's attempt.

A further controversial issue is whether the federal government should be allowed to pre-empt local legislation. The bill's final position on this is likely to be the outcome of lengthy discussion with members of Congress and the administration.

But even if this approach fails to break the current deadlock, there is still a chance that the administration could develop a regulatory framework for both publicly and privately funded recombinant DNA research through existing legislation, namely section 361 of the Public Health Act.

Although the government had previously stated, following a petition from the Environmental Protection Fund in 1976, that it felt this legislation did not cover DNA research, recent re-examination of previous issues to which the act has been applied has indicated that this may indeed be possible.

Speaking at hearings held in

Washington last November by Senator Adlai Stevenson, Dr Gilbert Omenn of the President's Office of Science and Technology Policy said that the administration had rejected section 361 as being neither appropriate nor sufficient for recombinant DNA research.

However after looking at some of the previous applications more closely, the administration is beginning to have second thoughts, and is now looking closely at ways in which, if congress fails to come up with the appropriate legislation, regulations covering research with recombinant DNA could be implemented under section 361.

Tsiolkovskii's dream

THE link-up of Salyut-6 and Soyuz-26 and 27 marks a further step towards Tsiolkovskii's dream of a permanent orbital space station. Yet, rather strangely, the link-up was not used to effect a change of personnel, but merely to simulate one; the second crew—Vladimir Dzhanibekov and Oleg Makarov—returning to earth only five days after launch, and leaving the veterans—Yurii Romanenko and Georgii Grechko—still in orbit.

Salyut-6, with its two docking bays, represents a new generation of Soviet spacecraft. The docking bays are interchangeable, so that when Soyuz-25 failed to dock and it was suspected that there was some fault in the docking equipment, Soyuz-26, as back-up mission, docked in the second bay. Only after Romanenko and Grechko had checked out the first bay was this used for the linkup of Soyuz-27. Although there was no actual change of crew, the returning cosmonauts did change spacecraft, returning to earth aboard Soyuz-26. The launch of the second crew one month to the day after the first may be some indication of the shift-length planned for a fully operational space station; such a station, it is stressed, could save considerably on the time at present spent in warming up and mothballing the station at the beginning and end of singleton missions.

In addition to comforts for the "resident" crew—books, mail, newspapers—and the cherry juice required for the ritual toast—the "relieving" Soyuz-27 carried two temperature-stable "Biotech-8" containers containing, respectively, the paramecium and proteus cultures for the Franco-Soviet "Cytos" experiment, which studies the effect of space-flight on cell-division. The "visiting" crew also

carried out a study of blood circulation, data from which, it is hoped, can be used to develop prophylactic measures to help cosmonauts adapt to weightlessness. Dzhanibekov, an expert on radioelectronics, checked out the various on-board systems, and all four took part in the mechanical "resonance" experiment to determine the exact strength characteristic of the compound structure.

With mail delivered again to orbit (the first time since the Soyuz 4/5 linkup of 1969), a radiorepair man on call, and (according to veteran cosmonaut Valerii Kubasov) plans for refuelling the correction engines already under discussion, Tsiolkovskii's vision seems perceptibly nearer. Yet in one respect, Salyut-6 would seem to represent a retrograde step. Although, according to Grechko, the work aboard Salyut-6 is more interesting than his previous mission on Salyut-4, since the cosmonauts can now go for spacewalks, nevertheless he misses the "oasis, where we grow plants and peas" of the earlier craft.

Vera Rich

US industry attacks Ames test

SHORT-TERM bacterial tests for potential carcinogens, such as that developed by Dr Bruce Ames at the University of California, do not predict similar responses in humans, according to the American Industrial Health Council, a New York based lobby group for the US chemical industry.

In comments on legislation covering the industrial use of potential and known carcinogens proposed by the Occupational Safety and Health Administration, the council, whose members include representatives of the

major US chemical companies, says that while such tests have value as screening tools, they are too unreliable as predictors of human responses to be sufficient to warrant regulatory action.

The council recommends that emphasis should be placed both on data from animals exposed to low levels of potential carcinogens over normal lifespans, and where prior worker exposure has occurred, on human epidemiological data. It rejects the notion that it is realistic to impose a "no risk" approach to potential carcinogens, and suggests rather the development of

dose-risk data, using risk/benefit analysis to determine acceptable-risk levels of exposure.

The council also suggests that the National Academy of Sciences should set up a classification panel to examine the hazards of potential and known carcinogens, which would be responsible both for proper category assignments and for the modification of categories as relevant advances in science dictate.

AIHC believes that setting up such a panel would provide some degree of insulation from a wide variety of

"political and other pressures" to which regulatory agencies are subject, requiring such agencies to make politically-acceptable decisions and to pay "somewhat less attention" to their scientific basis.

"The classification of carcinogens is a scientific, not a regulatory question, and would be much better handled by an independent group of scientific people than by a regulatory agency" according to Dr Ellwood P. Blanchard of the Dupont Company, a member of the AIHC steering committee.

Dioxin meeting recommends cancer study

SINCE the release of dioxin (the isomer 2, 3, 7, 8 tetrachloro dibenzo-p-dioxin) over a populated area at Seveso in Italy on 10 July 1976, there has been fear that the chemical is a carcinogen. Few data have been available, but it is beginning to seem that the fear is justified; hence the meeting in Lyons last week hosted by the International Agency for Research in Cancer (IARC) and the US National Institute of Environmental Health Sciences. The conclusion of the meeting was that a major epidemiological survey should be established.

It is now known that there have been at least 14 incidents in different chemical plants throughout the world where workers have been exposed to chlorinated dibenzo dioxin. In two cases the public has been exposed: at Seveso and in the herbicide spraying programme in Vietnam. In the latter cases large populations were exposed to low levels of dioxin; but while these populations must be monitored to assess the public health risk associated with low level exposure, at Lyons the opinion was that little could be learned from them. If dioxin exposure was to be unambiguously related to clinical and pathological findings, the meeting argued, the chemical plant workers were the group to monitor.

Three of the industrial accidents discussed in Lyons occurred between 20 and 30 years ago. Evidence is available from one of these accidents to suggest that in recent years there has been a marked increase in certain types of carcinoma in workers exposed to dioxins.

However the importance of this finding is marred by the small numbers of workers monitored. The meeting considered that it was therefore an urgent matter for a larger population to be studied to detect trends in carcinoma incidence which would be statistically significant. It urged the

chemical companies concerned to make their records available for scrutiny. And the meeting stated in no uncertain terms that all the workers exposed to dioxin—whether they are still employed by companies or employed elsewhere—must be located. Mortality trends for this population must be collected.

Two groups reported animal studies to test the carcinogenicity of dioxin: the first directed by Dr James Allen at the University of Wisconsin, and the second by the Doll Chemical Company. Both research teams identified the dioxin as a carcinogen. But the Wisconsin team claims that the chemical is carcinogenic at a concentration 700 times lower than the level that produce tumours in Doll's study. Reasons for the discrepancy are still not clear, but it was pointed out at the meeting that the Wisconsin study is based on an extremely low number of animals.

Some of the companies involved in dioxin accidents fear further independent investigation, not wishing to run the risk of vast compensation claims. And the meeting felt that, if companies made it a condition that their participation in a dioxin workers' survey were to be treated in confidence, this wish must be respected. The view was that, wherever the blame lies, the most important task at the moment is the compilation of information; and this the IARC is willing to undertake. Dr Rodolfo Saracci of the Unit of Immunology and Bio-Statistics agreed to direct some of this work.

The IARC will act as a clearing house for data on chlorinated dibenzo dioxin—with the help of a permanent secretariat co-opted from participants at the meeting. One of its first tasks will be the production of a list of recommended clinical procedures for examining people exposed to dioxin. It will be stressed that where possible the

clinical findings should be related to body dioxin levels—the 'body burden'. This information together with the mortality data should leave the IARC better able to assess the danger to health caused by exposure to dioxins; cancer may be only one of the possible risks.

Alistair Hay

NASA chooses its space lab candidates

FOLLOWING a similar announcement from the European Space Agency (*Nature*, January 5), the US National Aeronautics and Space Administration has announced the six American scientists from whom one will be selected as a payload specialist on the first flight of Spacelab, due to be flown in NASA's Space Shuttle in 1980.

The names of the finalists are:

Dr Craig L. Fischer (40), of the Palm Desert Medical Group Inc, California; Dr Michael L. Lampton (36), of the University of California, Berkeley; Byron K. Lichtenberg (29), Massachusetts Institute of Technology; Dr Robert T. Menzies (34), NASA Jet Propulsion Laboratory, Pasadena, California; Ann F. Whittaker (38), NASA, Marshall Space Flight Center, Huntsville; and Dr Richard J. Terrile (26), California Institute of Technology, Pasadena.

Five of the ten candidates that have now been named by NASA and ESA will undergo extensive training following a final selection in early spring. Of these, two will go into space, while the other three will perform support and advisory roles in the control centre on earth. □

Government accuses nuclear industry of using propaganda

THE US Government has accused its industrial partner in its fast breeder reactor development project at Clinch River, Tennessee, of producing pam-

phlets that give an "oversimplified" and "distorted" view of the dangers of nuclear power.

In a report published in Washington last week, the General Accounting Office said that the Breeder Reaction Corporation of Oak Ridge, Tennessee, which represents almost 700 companies involved in the fast breeder programme, had produced a series of thirteen pamphlets about the programme, at least four of which "clearly constitute propaganda and as such are questionable for dissemination to the public".

In particular, the GAO questioned the statement in one pamphlet that plutonium is "not a realistic threat when compared with other hazardous materials". It says that the pamphlet grossly understates the dangers, and does not inform readers that plutonium is extremely toxic, and in some circumstances carcinogenic. □

US ban use of prisoners in drug research

THE US Department of Health, Education and Welfare is planning to ban the use of prisoners for drug research not directly related to their health or well-being.

This suggestion follows last year's report of the Commission for the Protection of Human Subjects of Biomedical and Behavioural Research, suggesting stringent conditions on such research to ensure that the participation of prisoners was voluntary.

In its response to comments on the Commission's report, published last week (January 6), the department says that the Commission found "a paucity of evidence" that research testing of drugs involving minimal risk on prisoners was necessary (see p. 197).

In issuing proposed regulations on research involving prisoners, the department has therefore suggested that the use of prisoners for biomedical and behavioural research studies other than those relating directly to the causes and conditions of their imprisonment, and their well-being in prison, should be banned.

"The Department has concluded that the need to assure that research on human individuals is performed only on human subjects is performed only on individuals who have knowingly and voluntarily consented to participate far outweighs any need that has been shown for the use of prisoners in these studies" it says.

David Dickson

THE high rate of rickets in children of Asian origin in Britain is causing concern, and a demand that the government "does something about it". One suggestion is that various foods including the flour used to make chapatis, should be fortified with vitamin D. This proposal is being resisted by some scientists, because the present addition of calcium and vitamins to bread, and of vitamins to margarine, is now under attack. It is pointed out that there is little or no evidence that this costly and complicated scheme is having any beneficial effect on the nutritional standards of the population, and that more experimental evidence should be sought. It is probable that if every Asian child in Britain took a spoonful of codliver oil daily, rickets would disappear among this section of our population. Efforts to ensure that the vitamin went where it was needed would be more effective than giving everyone unnecessary and unwanted supplements.

Those who favour more mass fortification of food have the mistaken belief that as we all need small amounts of substances like vitamin D to preserve our health, then the more we consume of them the healthier we will become. This false opinion is perpetuated by many advertisements. I have before me one which tells me this preparation is rich in protein, iron and vitamins B1 and B2. It goes on to say that protein is essential for growth and bodily repairs, iron to nourish the blood, and the vitamins to aid digestion, convert food to energy and to maintain tissues such as nerves, muscles and the skin, and generally to promote "vitality". Seed

Enough is enough

KENNETH MELLANBY

merchants tell us that the more expensive varieties of vegetables give plants particularly full of protein, and with extra amounts of vitamin C and minerals. Once again they claim that these substances must be taken if we are to remain healthy.

All these statements about the need to eat protein and vitamins are of course true, and if we were living on deficient diets the advertised commodities would no doubt do us good. But when our diet contains the required minimum of these substances, and addition is generally useless and often harmful.

Unfortunately in Britain it is often the better educated who talk the most

nonsense about diet. They have learned some of the elements of nutrition and know all about deficiency diseases. They seldom realise that most of our over-fed adults have a surplus of protein and other essentials, and that most of the allegedly health-giving supplements would be best flushed down the drain.

Yet malnutrition, in various forms, is common. In all Western countries the most common and obvious form is gluttony with consequent obesity. Those who try to slim by eating less are subject to a barrage of advertisements for low-calorie foods containing large amounts of supplements. These are generally unnecessary, for the slimmer lives on a nutritious diet of (his own) human flesh. Then the appalling state of our teeth is a symptom of some dietary imbalance, partly but not entirely connected with our overconsumption of sugar. But on the whole most adults seem not to be short of protein and vitamins, so more of these are not "good for them". The only common deficiency would seem to be fibre, and there is evidence to suggest that added bran does some good, but most supplements seem to be useless or harmful.

The position with young children and the elderly is rather different. These groups have a limited food intake, and in Britain today up to half of their calories may come from sugar, in sweetmeats for children, in hot sweet tea for the old. This leaves little room for essential nutrients, so it may be necessary to add these in concentrated form. But it would be more sensible to cut down on the sugar, which, in excess, is always harmful.

correspondence

Soviet genetics

SIR,—Dr Italo Barrai in his letter (*Nature* 271, 8; 1978) commenting on my earlier article on the new controversy on human genetics in the USSR (*Nature* 268, 285; 1977) asks me two questions which I shall answer here.

Barrai questions my ability to describe the situation in genetics "... what can a gerontologist say about human genetics: in what position is he to pass value judgement?"

It is true that most of my research while in the USSR and here in UK had been related to problems of ageing. However, my book *The Rise and Fall of T. D. Lysenko*, published by Columbia University Press in 1969 is still the only book written and published by a Russian scientist about the history of genetic controversy in the Soviet Union. This book also described the history of medical genetics in the USSR from 1920 to 1967. My article in *Nature* was in some way a continuation of these accounts.

Barrai's second question asks that I prove that in 1976 N. V. Tsitsin was not yet appointed president of the Genetic Congress (which takes place in Moscow in August 1978). The proof comes in the decision about the Moscow Congress made at the previous Congress in Berkeley in 1973. At this Congress D. K. Beliaev, in his capacity of the President of the Soviet Genetic Society, made an invitation on behalf of the Government of the USSR, to hold the next Congress in Moscow. As soon as the invitation was accepted D. K. Beliaev started to make all necessary arrangements as acting President. N. V. Tsitsin's name as president of the Congress appeared only in 1977, and I believe that it surprised not only me, but also the International Genetic Federation. N. V. Tsitsin, now 80 years old, was never very popular among geneticists, mostly because the way in which he acquired prominence in the mid-1930s. One can read about this in the book by Prof. D. Joravsky *The Lysenko Affair* (Harvard University Press: Boston, 1970)—

"In 1932 Tsitsin moved to the West Siberian Experimental Station in Omsk, whose director, V. R. Berg, believed in the practicality of crossing wheat with couch grass. He had been

working on the problem himself.

"A year after Tsitsin's arrival in Omsk, Berg was arrested as a 'wrecker', and Tsitsin was made a hero by the mass media, even though (or because) he still complained that 'an enormous portion of specialists up to the present are extremely negatively inclined toward our work.' A commission of inquiry from the Commissariat of Agriculture, which was itself being purged of 'wreckers', decided that Tsitsin's work had enormous promise and merited great support. He was given space in *Pravda* to promise an annual hybrid of wheat and couch grass ready for production testing by the fall of 1935; a perennial would take a year longer. When 1935 came to an end without a hybrid ready for the testing service, Tsitsin received reassurance from the highest authority. Stalin told him, and allowed the awesome words to be inscribed on newsprint: 'Experiment more boldly. We will support you'. Tsitsin became the director of the Omsk station, which had been promoted into the Siberian Institute of Grain Culture. Specialists began to pay respectful attention to his work."

Everything in this description is correct. One can find details of the events in *Pravda* for 9 July 1934 and 30 December 1935, pp. 81–82. N. V. Tsitsin has still not made perennial wheat, but as a director of a big plant breeding research institute after the second world war he could be given credit for some achievements in wheat breeding. He has not played any serious role in Soviet genetics for the last five years; and his name was removed from the editorial board of the Soviet journal *Genetika* at the very beginning of 1973. If Soviet geneticists had had a free choice of who was to be president of the first International Congress on Genetics held in the USSR I doubt very much that Tsitsin would have got the job.

Dr Barrai also asked me to give a fuller justification of my negative assessment of N. P. Dubinin's current work. I am afraid that this needs more space than this letter permits. Dr Barrai, however, partly provided the answer himself. Trying to explain some false methods in N. P. Dubinin's publications Dr Barrai wrote "... it might well be that, as director, he signs work from his institute which might be

beyond the capacity of his technical judgement". Some of my colleagues in the USSR also thought that this could be the case. They thought, however, that this could equally be said about publications which were not failures. In any case the Moscow Congress will provide enough information about the situation in Soviet genetics today for those who do not restrict their interest to the official programme.

Yours faithfully,

ZHORES A. MEDVEDEV

National Institute for
Medical Research, London

NIH guideline ineffective

SIR,—The National Institute of Health *Guidelines for Recombinant DNA Research* recommended 2% aqueous Wescodyne, an iodophore that is used in many hospitals and laboratories as a disinfectant, as a decontaminant for biological safety cabinets and 5% for a spill outside a cabinet. A contact time of 10 to 15 minutes was given for the 2% solution and 20 minutes was considered adequate for the 5% concentration.

However I have conducted experiments which indicate:

- Aqueous Wescodyne (5%) is ineffective when used for 80 minutes against poliovirus in a test mixture containing 8.5% bovine serum albumin (a mixture equivalent in protein concentration to the higher range in serum).
- Wescodyne (10%) employed under the same conditions for 40 minutes is also ineffective.
- Wescodyne (10% v/v) in 50% ethanol (w/w) was effective and this mixture, originally recommended for hand washing, should be considered for use in biohazard situations, particularly for decontamination of work surfaces and biological safety cabinets.

These results are significant, for if a virucide cannot inactivate poliovirus one would be concerned about using the virucide against hepatitis B or SV40 viruses.

Yours faithfully,

ALFRED M. WALLBANK

The University of Manitoba,
Winnipeg, Canada

Pseudogene structure in 5S RNA genes

from Peter Ford

THE 5S RNA genes of *Xenopus laevis* have several obvious advantages as a system for studying specific gene regulation in higher eukaryotes. The 5S RNA itself is a small (120 nucleotides) readily purified molecule which is easy to identify by simple sequencing techniques. As a component of ribosomes it is found throughout the living world and has an essential though poorly understood function in protein synthesis. It is synthesised in its final form with no obligatory processing at either 5' or 3' terminus unlike most other RNA species, which means that correct termination and more important correct initiation of transcription may be easily assayed. In addition *Xenopus laevis* expresses different sets of 5S RNA genes in somatic cells and oocytes, a property which is phylogenetically widespread since it also occurs in other amphibians and teleost fish, and implies a general mechanism by which differential 5S gene expression is controlled. No one understands at present the functional significance, if any, of different 5S RNA sequence variants in oocytes and somatic cells, and for the purposes of understanding gene regulation this is not important.

D. Brown and his collaborators reported the purification of 5S DNA from *Xenopus laevis* a number of years ago (Brown, Wensink & Jordan *Proc. natn. Acad. Sci. U.S.A.* **68**, 3175; 1971). The genes are highly repeated (24,000 per haploid genome) and tandemly linked into several clusters (perhaps as many as 18) at the ends (telomeres) of chromosomes (Pardue, Brown & Birnstiel *Chromosoma* **42**, 191; 1973). As it turned out the purified 5S DNA prepared by Brown is of the oocyte type, the somatic type has not so far been isolated from *Xenopus laevis*, which means that the work done so far on purified 5S DNA relates only to the oocyte type sequences. The bulk of the

purified 5S DNA has a regular alternation of AT-rich with GC-rich sequence within each repeating unit which is about 700 base pairs long. Although different repeating units are very similar to each other they may differ in length and in sequence detail. Length heterogeneity has a quantal element resulting from a variable number of a 15 base pair mini repeat located in the AT-rich region but is complicated by presence or absence of other specific AT-rich sequences. The GC-rich region which contains a single 5S RNA gene is very constant in length (350 base pairs) but may vary in sequence detail.

What has come as a surprise to many people is the recent demonstration by two independent sequencing techniques (Jacq, Miller & Brownlee *Cell* **12**, 109; 1977; Fedoroff & Brown *Cold Spring Harbor Symp. quant. Biol.* **42**, in the press) that the GC-rich region of 5S DNA also contains a pseudogene which is identical to the first 101 base pairs of the gene at all but 10 sites. The pseudogene completely lacks the last 19 base pairs of the gene. The pseudogene is detected in both total genomic 5S DNA as well as in purified individual repeat units cloned in bacterial plasmid vectors and can thus be assumed to occur in the majority if not all of the repeat units in oocyte type 5S DNA. A map of the repeat unit now looks like this

Attempts to show that the pseudogene is transcribed *in vivo* have not been successful suggesting that pseudogenes are not transcribed or that their transcription products are very short lived. Until positive evidence for pseudogene transcription is found it seems reasonable to assume that they are inactive. Now both the gene and

the pseudogene are preceded by GC-rich sequences 49 base pairs long which are identical in all but nine positions. By analogy with prokaryote systems the region preceding a gene is expected to contain promoter sites for RNA polymerase binding and perhaps regulatory sites for the control of transcription. Since all the information required for the correct initiation and faithful transcription of the 5S gene is present within one repeat unit as was shown by the successful and faithful transcription of cloned single repeat units after microinjection into *Xenopus* oocyte nuclei (Brown & Gurdon *Proc. natn. Acad. Sci. U.S.A.* **74**, 2064; 1977; Fedoroff & Brown *op. cit.*), it seems reasonable to conclude that the specific absence of pseudogene transcription is due to the absence of the information required for initiation of transcription in the pseudogene. This means that either the information for correct polymerase binding resides in the AT-rich region which comes before the GC-rich 'promoter' region of the gene or it has been specifically destroyed by some or all of the nine base changes which differentiate the 'promoter' region of the pseudogene.

The sequence for a 5S gene region from the budding yeast, *Saccharomyces cerevisiae*, has been determined recently (Valenzuela *et al.* *Nature* **267**, 641; 1977; Maxam *et al.* *Nature* **267**, 643; 1977) and it may be instructive to compare the 'promoter' region with that found in *Xenopus*. The rationale for this comparison lies with the observation that prokaryote promoters show AT-rich regions which by mutation analysis are known to be involved in polymerase binding. One site which allows initial recognition and entry of the polymerase is located about 30–35 nucleotide pairs upstream from the origin of transcription. A second AT-rich site, the tight binding site, is located 10 nucleotide pairs from the origin of transcription. There is some but not a great deal of sequence con-

servation at these sites when different promoters are compared. Comparison of the yeast and *Xenopus* 'promoters' shows very little sequence similarity as expected, but there are two structural features in common and only future work will show if they are significant. A sequence with twofold rotational symmetry is centred 11 (yeast) and 12 (*Xenopus*) base pairs from the origin of transcription and contains a CCG sequence off centre. The second feature is the presence of an AT-rich region seven nucleotides long which has a trinucleotide in common and is centred 27 base pairs away from the origin of transcription. Both these sequences are mutated in the pseudogene 'promoter' consistent with the notion that they are important in the normal faithful origin of transcription.

The presence of an inactive pseudogene presents an evolutionary paradox. Since it is not transcribed it is prob-

ably non-functional although it may have some other unknown function for which it has been selected and preserved in evolution (Jacq *et al. op. cit.*), but the mutations which make it non-functional are present in every copy and must have arisen once in the original pseudogene. The alternative that the same mutations have occurred many times at the same sites in different pseudogenes is not only unattractive but a highly improbable set of events. As it now exists the pseudogene sequence would produce a partial 5S molecule which might compete with the normal product for ribosome binding but render such ribosomes inactive or inefficient in protein synthesis. There would be heavy selection against such a gene activity and mutations would rapidly accumulate to inactivate or eliminate the pseudogene. The evolutionary paradox is thus seen as a question how can a functionless

potentially deleterious sequence spread in a genome to the extent that the 5S pseudogene has spread as if selected for some particular purpose? Could it be as Fedoroff and Brown suggest that the events leading to the spread of the gene itself have also led to the spread of the pseudogene as an unwitting 'fellow traveller of an evolutionarily successful gene'?

Whatever the actual evolutionary history of the pseudogene it is clear that future work will establish the regions essential for polymerase binding and possibly for control elements in 5S DNA. Such experiments will make use of the *Xenopus* oocyte nucleus as a vehicle for testing mutated and mutilated cloned 5S DNA repeats. What of tissue specific control? It would be useful to have the somatic type 5S DNA cloned and purified for comparison but that is another story and must wait for another day. □

Rhizobium recognition

from John E. Beringer

ALL *Rhizobium* species have the capability to form nitrogen-fixing nodules on the roots of leguminous plants. However, not all legumes are nodulated and those that are usually interact only with a particular 'species' of *Rhizobium*. This host-range specificity has long been an intriguing problem but, until recently, little was known about its biochemical basis. An understanding of the mechanisms should not only enhance our knowledge of the symbiosis, but also indicate ways in which *Rhizobium* and plant species may be manipulated genetically to increase the range of nodulated plants.

It is thought that host range is determined before the bacteria penetrate the surface layers of the root and that it is based on the specific recognition of the 'correct' *Rhizobium* species by the plant in a manner analogous to antigen-antibody binding. What makes this an attractive model for the host-range interaction is the observation that plants produce compounds called lectins that are able to bind to 'antigens' and are known to play a part in the plant's defence mechanism against pathogenic microorganisms.

The lipopolysaccharides of Gram-negative bacteria are well known antigens, primarily because they include the O antigens of *Salmonella* species. The rhizobia are Gram-negative bacteria and share the same general pattern of surface structure as the salmonellae. Working outward from the cytoplasm this includes a mucopeptide layer, then lipopolysaccharide, often a polysaccharide capsule and sometimes a further, less adherent, layer of structurally fairly simple exopolysaccharide. Because lipopolysaccharides are known antigens it might be expected that if there are host-specific antigens recognised by legumes they would reside in this layer of the cell wall.

There have been a number of reports in the literature which indicate that lectin binding by *Rhizobium* species may be involved in the host-symbiont recognition process. Dazzo and Hubbell (*Appl. Microbiol.* 30, 1017; 1975) have even produced a model for the recognition process based on the observation that a common antigen occurs on the surfaces of the roots of clover and on nodulating strains of *R. trifolii*. They suggested that the binding of multivalent lectins to these common antigens could be the method whereby the cor-

rect host and *Rhizobium* species were brought into close contact, allowing the interaction to proceed to a point where penetration could occur. Despite anomalies that have been reported in lectin-*Rhizobium* binding studies, it is now generally accepted that recognition is likely to involve lectin binding.

Having shown that lectin binding was important, an obvious step was to determine the nature of the bacterial antigen(s). Dazzo and Hubbell suggested that the antigenic determinant(s) of *R. trifolii* strains resided in the capsular polysaccharide and later Dazzo and Brill (*Appl. environ. Microbiol.* 33, 132; 1977) reported that this binding was mediated through 2-deoxyglucose-sensitive binding sites present on clover root hairs and in the capsular polysaccharide of nodulating *R. trifolii* strains. They also isolated the binding protein (lectin) of clover which bound to *R. trifolii* but not to two species which do not nodulate clover, *R. meliloti* and *R. japonicum*. This attractive piece of research served to indicate that at least the initial stages of host-symbiont recognition were simply based on the presence of a common receptor in the surface layers of the host and bacterium. However, the situation is not so clear because Wolpert and

Albersheim (*Biochem. biophys. Res. Commun.* **70**, 729; 1976) have reported that legume lectins interact with the lipopolysaccharide of their 'correct' *Rhizobium* species.

A classic way to examine the importance of cell wall components for antigenicity or phage attachment has been to examine mutants defective in their synthesis. This approach has been taken by Sanders, Carlson and Albersheim who report their findings with *R. leguminosarum* in this issue of *Nature* (page 240). By selecting bacteria after passing cultures through 1.2 μ m Millipore filters they obtained mutants at high frequency which did not produce exopolysaccharide. Chemical characterisation of the mutants indicated that there was no exopolysaccharide synthesised and that the capsule and lipopolysaccharide were unaltered. Five of these mutants, otherwise apparently indistinguishable from the parent, were tested for their ability to nodulate their correct host plant, the pea; all five mutants were non-nodulating. Five spontaneous revertants of one of these mutants, selected for the reappearance of exopolysaccharide production, all regained the ability to nodulate the pea. Thus it appears that the exopolysaccharide is essential for nodulation to occur, at least in this strain of *R. leguminosarum*. Whether or not it is involved in lectin binding has not yet been determined.

It now remains for these and other workers to clarify the rôle of capsular, lipo- and exopolysaccharides in determining the host range of *Rhizobium* species. Indeed it has yet to be shown how complex the host recognition process is. Perhaps lectin binding is only one of a complex series of recognition processes that must occur before a nitrogen fixing nodule can develop. □

Mining triggers earthquakes

from Peter J. Smith

It is almost universally accepted now that, given the right circumstances, earthquakes may be induced artificially by injecting fluids into the ground, by setting of underground nuclear explosions or by filling large reservoirs. Indeed, the idea is so commonplace that there may be some difficulty in believing that less than 7 years ago it was the subject of lively controversy, largely because the evidence in favour of man-made earthquakes, though strong, was then little more than cir-

Animal sounds: coloratura and basso profundo

from John Krebs

MANY species of birds and mammals use sounds as threat signals in contests over territory and other resources. Dogs growl, elephants roar, and great tits scold. The remarkable thing is that the threat sounds of most birds and mammals tend to be low-pitched, harsh (broad frequency spectrum) noises. In contrast non-aggressive signals, such as appeasement gestures, tend to be high pitched and contain pure tones. E. S. Morton (*Am. Nat.* **111**, 855; 1977) now suggests an explanation.

Threat signals in the animal world to some extent replace out-and-out fighting, presumably because it is less dangerous for an individual to settle a dispute in this way. But obviously the loser of the contest, which might be for example over a piece of food, does less well than the winner and so one might expect, anthropomorphically speaking, losers not to give up easily when faced with a threat signal unless they are sure that they would lose eventually. The inescapable conclusion is that at the beginning of a contest animals try to assess the fighting ability of their opponent without actually engaging in a scrap. What sort of cues therefore would give reliable information about an opponent's fighting ability? A totally arbitrary cue would be easily faked, but some body features are inevitably correlated with strength, an obvious example being body size.

The significance of low pitched threat sounds should now be apparent: on the whole, larger individuals are capable of producing lower pitched sounds. The pitch of a threat call depends on the tension, size and thickness of the vibrating membrane on the voice box, and at least in mammals, on the volume of the nasal and oral cavities which act as resonators. In other words, depth of voice gives a quick, rough indication of how big an opponent is, and so it is not surprising that low pitched sounds have, during evolution, become an effective way of threatening a rival. Harshness is often an inevitable by-product of low frequency sounds, since a vibrating membrane under low tension will tend to produce harmonically

unrelated tones.

Why should appeasement and non-aggressive sounds be high pitched? One possibility is Darwin's Principle of Antithesis—signals conveying opposite kinds of information tend to be very different to reduce confusion—but Morton also suggests that high pitched appeasement calls have, so to speak, parasitised the fact that animals respond in a non-aggressive way to the high pitched begging calls of their young.

Coloratura, according to my dictionary, refers to 'incidental trills introduced to make a song or other piece of music more agreeable.' The song of our common or garden wren (known across the Atlantic as the winter wren) has enough coloratura to make Rossini's *Una voce poca fa* sound like a Gregorian Chant, but does this make it more agreeable to other wrens? D. Kroodsma (*Am. Nat.* **111**, 995; 1977), suggests that it does. He studied song recordings of the nine species of North American wren, which show a considerable range of complexity. Virtuosi such as the long-billed wren have over 100 different song types for each individual male, while the less ostentatious male Bewick's wren has between 9 and 20 song types. Kroodsma calculated for each of his nine species an index of song virtuosity, including information about the number of song types and the complexity of each type (for example our own wren has few song types but each one is very long and complex, so this species scores high on overall virtuosity.)

One conclusion of this analysis is that wren species with the most complicated songs are those species in which males are most polygynous. In polygynous species, the males compete intensely for females to add to their harems, and as the females have a choice of mate, they exert powerful sexual selection on males. Any male trait which increases his attractiveness to females will be favoured, and it seems that coloratura singing in wrens is just such a trait. It is an auditory peacock's tail.

John Krebs is a lecturer in Zoology at the Edward Grey Institute, University of Oxford.

cumstantial. What was lacking in most cases was a detailed record of seismic conditions for the period before the suspect events had become quite ob-

vious even to the least sensitive member of the population. In short, 'before and after' seismic comparisons were generally not available—a data gap

which led inevitably to a credibility gap.

Thanks largely to the controlled experiments at the Rangely oil field in Colorado (see for example Raleigh *et al. Science*, **191**, 1230; 1976) and the wider recognition of the role played by fluids in seismic processes generally, the reality of man-made earthquakes is no longer in doubt. Nevertheless, well-documented examples of the onset of such events are still quite rare, which makes the observations in western New York state by Fletcher and Sykes (*J. geophys. Res.* **82**, 3767; 1977) of more than routine interest. They also exemplify astonishing good luck. Fletcher and Sykes set up their seismometer array in 1970 in anticipation of the injection of fluids into a deep well at a steel plant just south of Buffalo. The planned injection never actually took place, but seismic activity increased anyway. What Fletcher and Sykes were unaware of at the time was that a hydraulic salt-mining operation was about to begin nearby at Dale, New York.

As it happens, the Attica-Dale area is already the most seismically active region of western New York state, but only in that there is a history of isolated, moderately large earthquakes. There have apparently been no swarms of smaller events in the recent past; and certainly none was recorded by Fletcher and Sykes from June 1970 to early August 1971, a period during which there was an average of only one seismic event a month. Unfortunately, the recording equipment was out of action for much of August, September and October 1971; but when normal service was resumed at the end of October, Fletcher and Sykes found they were observing microearthquakes at rates of up to 80 a day. The contrast with the year to August 1971 was startling.

The foci of these events were found to lie in the vicinity of a high-pressure injection well used in the hydraulic mining of salt. If Fletcher and Sykes had known of this operation in advance they would probably have taken greater care to have their recording apparatus in working order at the crucial time in early August 1971 when the well pressure was raised to its maximum of more than 60 bars. As it was, the onset of pressure-induced earthquakes went largely unrecorded. On the other hand, there is little doubt that the high activity observed from October onwards was the result of well fluid pressure, for when that pressure was allowed to fall suddenly to below 10 bars in mid-November the microearthquakes ceased equally spectacularly.

An important clue to the direct origin of the earthquakes comes from their distribution, for their foci lie not

only close to the injection well but also in an elongated zone along the Clarendon-Linden fault which passes within 50 m of the well bottom. The

obvious interpretation is that increase in pore pressure resulting from hydraulic mining triggered seismic activity in the Clarendon-Linden fault zone. □

Functions of the septo-hippocampal system

from A. H. Black

The Ciba Symposium on the Functions of the Septo-Hippocampal System was held in London on October 17-20, 1977. The proceedings will be published as Ciba Foundation Symposium 58 (Elsevier/Excerpta Medica/North Holland, Amsterdam and New York, 1978). The symposium was organised by Dr J. A. Gray and chaired by Dr L. Weiskrantz.

ALTHOUGH considerable attention was focused on the anatomy and physiology of the septo-hippocampal system, the symposium was primarily concerned with behavioural functions. Let me first point to a difference between the septum and hippocampus. Both H. Ursin (University of Bergen) and S. P. Grossman (University of Chicago), who described research into the effects of septal damage, argued that the septum was a complex structure involved in a number of different, perhaps unrelated, behavioural control circuits, and, therefore, that one could not ascribe a single or even a few functions to it. On the other hand, the discussion of the hippocampus (and those areas of the septum to which it was intimately connected) suggested that it might carry out a small number of related functions. I shall focus on the discussion of those functions.

There was little support for the hypothesis that the primary function of the hippocampus is to inhibit behaviour. This hypothesis dominated the non-human literature in the late 1960s and early 1970s. Its relatively sudden demise (perhaps only temporary) is all the more striking. Three other possible functions of the hippocampus received considerable attention. The first was the plasticity of the hippocampus and its possible role in learning. P. Andersen (University of Oslo) presented some elegant data on

the synaptic potentiation that follows repetitive stimulation in isolated transverse slices of hippocampal tissue. After short periods of tetanic stimulation of isolated input fibres to CA1 cells there was a long lasting (from 30 to 75 min) increase in the extracellular excitatory postsynaptic potential recorded from the apical dendrites. Also, single units showed a corresponding increase in their probability of firing. These changes were seen without any change in the size of the afferent fibre volley. These results indicated that the potentiation could be attributed to changes at the synapse—either to an increased amount of transmitter or to a changed postsynaptic resistance locally in the dendritic tree. Additional data on the plasticity of the hippocampus were provided by G. Lynch (University of California) from an experiment in the freely moving unanaesthetised rat. The rats were first trained to press a lever when a tone was sounded. During the course of such training an evoked potential recorded from the outer molecular layer of the dentate gyrus gradually developed to the tone. After training to a single tone had been completed, the rats were trained to discriminate between two tones. The evoked potential was now seen to both tones, and the tones elicited discharge of the granule cells even though they had not done so before. At first, fairly long bursts of single unit activity were observed to both tones. But, as time passed, long bursts of firing to the reinforced tone continued while the burst of firing to the non-reinforced tone decreased in duration. Lynch suggested that these results are consistent with the view that the tones produce an input to the hippocampus by way of the perforant path; the effects of the input increase gradually during the early stages of learning—perhaps by the mechanism described by Andersen above, and earlier by Bliss and Lomo. Whether this input results in cellular discharge depends, however,

A. H. Black is Professor of Psychology, McMaster University, Hamilton, Ontario.

MANY plants, particularly aquatic ones, experience periodic or even permanent waterlogging in their environment. The selective advantages conferred by morphological adaptation to such conditions is evidenced by the widespread occurrence of lacunae and large intercellular spaces within aquatic species. It has been demonstrated that oxygen penetrates along such interconnecting channels, reaching the root or rhizome extremities. For example, Coult and Vallance (*J. exp. Bot.* **9**, 384; 1958) showed that oxygen moved the full length of a 45-cm rhizome of *Menyanthes trifoliata* when it was suspended in an oxygen-free atmosphere but with the leafy shoot exposed to air.

Individual cells, nevertheless, may find themselves in conditions of low oxygen tension. Under such conditions, metabolic adaptations are essential, particularly the avoidance of ethanol accumulation as a result of anaerobic glycolysis. McManmon and Crawford (*New Phytol.* **70**, 299; 1971) examined a range of flood-tolerant and flood-intolerant species under waterlogged conditions and they found that some species, such as *Pisum sativum* and *Vicia faba* which are flood-intolerant, showed greatly increased levels of alcohol dehydrogenase (ARH, involved in acetaldehyde to ethanol conversion) under flood conditions and also high activity of 'malic' enzyme which converts malate to pyruvate (which can then be converted to acetaldehyde and hence to ethanol). Flood-tolerant species, such as *Phalaris arundinacea* and *Glyceria maxima* were found to decrease in their ADH activities as a response to flooding and showed no activity of 'malic' enzyme.

McManmon and Crawford proposed that flood-tolerant species lack malic

Adaptations to waterlogged environments

from Peter D. Moore

enzyme so that a diversion of glycolysis to malate production does not result in further malate decarboxylation to rejoin the path of anaerobic glycolysis and ethanol production, but ends in malate accumulation. Malate build-up seems to be harmless in these cells. In the flood-intolerant species any malate produced is decarboxylated by 'malic' enzyme, ADH is induced and ethanol accumulates to the detriment of the cell membranes.

Crawford and Bains (*New Phytol.* **79**, 519; 1977) have recently demonstrated that the build-up of ethanol in the roots of forest trees on waterlogging varies from one species to another. Thus, in the Sitka spruce (*Picea sitchensis*) which is intolerant of flooding, ethanol concentration had increased to 12 times its original level (to 5.6 $\mu\text{mol per g}$ fresh weight) after 24 h in anaerobic conditions, whereas in *Pinus contorta*, a flood-tolerant species, ethanol accumulation increased only three times its base level (0.7 $\mu\text{mol per g}$ fresh weight). Once again, tolerance to flooding is associated with a control of ethanol accumulation.

Crawford has now (*New Phytol.* **79**, 511; 1977) examined the response of certain seeds to anoxia, for some mire plants can survive for considerable periods as seeds in anaerobic environments. For example the seeds of the rush *Juncus effusus* are reputed to germinate after 7 years submergence.

Sensitivity to prolonged soaking was found to vary with species. Rice seed viability was unaffected by a 6 h soaking, broad bean was reduced to 40% and pea was rendered completely non-viable after such periods.

In the species intolerant of soaking, such as pea and maize, ethanol was always found to be the major product of glycolysis under anaerobic conditions. Malic acid did not accumulate, but lactate was high in the early stages of glycolysis in broad bean and rice, the species tolerant of soaking. Ethanol production, however, exceeded lactate in even these species after 24 h soaking. The overall rate of glycolysis under anaerobic conditions was greater in the sensitive species, hence ethanol accumulated faster in these species.

Thus it would seem that the tolerance of seeds for prolonged immersion in water depends not upon any metabolic 'switch' as is the case for many roots, but upon the capacity to reduce overall metabolic rate. Crawford has further shown that for five out of six Gramineae species which he kept for 6 weeks as imbibed seeds under anaerobic conditions, there was a reduction in viability with increasing temperature. This would again suggest that increased metabolic activity leads to seed death, probably by ethanol accumulation and the associated membrane changes.

Crawford thus maintains that, although the precise metabolic techniques may vary between species and even between organs, the essential problem involved in the toleration of anaerobic conditions is the control and limitation of ethanol accumulation. □

Peter D. Moore is a Senior Lecturer in the Department of Plant Sciences, King's College, London.

on input through the second major afferent pathway to the hippocampus from the septum. Just what conditions lead to these plastic modulatory effects on the second input are not yet clear, however. Further research on these preparations should lead in the near future to a better understanding of plasticity in the hippocampus during learning.

The second function of the hippocampus that received considerable attention was its possible role in the detection of changed environmental circumstances, and in the behavioural adjustments that immediately follow the detection of such changes. While many participants agreed that the hippocampus is involved in the detection of change, they differed about the nature of the particular events whose change was detected. For example,

O. S. Vinogradova (USSR Academy of Sciences Biological Centre, Puschino-on-Oka) suggested that the hippocampus is involved in the detection of novelty (that is, any change in stimulus input), J. A. Gray (University of Oxford) that the hippocampus is involved in detecting changes in reinforcement schedule—in particular, from reward to non-reward, and J. O'Keefe (University College, London), on the basis of a theory that he and L. Nadel have proposed, suggested that the hippocampus is involved in setting up spatial maps of the environment and in detecting mismatches between the environment and the map when the former is changed. Given the extent of the agreement that the hippocampus plays a part in the detection of stimulus changes, one hopes that agreement as to the nature of these

changes is not too far off.

A third proposal was the hypothesis that the hippocampus is involved in certain types of spatial information processing. O'Keefe and A. H. Black (McMaster University) presented both single cell and lesion data in support of the O'Keefe and Nadel spatial theory of hippocampal function mentioned above. For example, certain hippocampal cells seem to fire only when a rat is in a particular location in a given environment, and their firing is independent of the rat's behaviour. D. Olton (Johns Hopkins University) also presented lesion data which were consistent with the view that the hippocampus is involved in spatial memory. He trained rats on an apparatus which consisted of a central circular platform from which eight arms radiated. Food pellets were placed

at the end of each arm. Normal rats very quickly learned to retrieve all eight pellets without re-entering an arm in which they had already found food. Rats with damage to the hippocampal formation failed to do this. But their performance, according to data provided by G. Winocur (Trent University, Ontario), improved if the floor of each of the eight arms was identified by a salient cue. It would seem that the lesioned rats could not employ spatial cues provided by the environment outside the maze to identify the location of each arm but could use specific non-spatial cues on the floor of each arm to do so. Although it is still too early to evaluate the spatial hypothesis, it seems to have aroused considerable interest—and controversy.

A final point concerns the problem of species differences. There are marked differences among species in a variety of aspects of hippocampal function, most of which are as yet unexplained. For example, the environmental events which elicited hippocampal single unit activity in the rabbit seem to differ markedly from those in the rat. Also, as C. Vanderwolf (University of Western Ontario) noted, more hippocampal theta electroencephalographic activity unrelated to movement occurs in the rabbit and cat than in the rat and dog. Perhaps the most important species differences are those between man and the other animals. A striking feature of the effects of hippocampal damage in man is an apparent memory deficit; experiments on the other animals show no memory deficit in most situations. Is this a real species difference or is it a procedural artefact? Winocur suggested that it was the latter. According to his view, after hippocampal damage subjects cannot use contextual cues properly to retrieve information in memory. The difference between man and the other animals arises because human subjects are usually tested on a series of learning tasks which interfere with each other unless contextual cues are used to isolate the tasks, while animals are tested on single tasks for which no interference occurs. Winocur argued that if the same type of task had been used in both cases, the deficit would have been similar. L. Weiskrantz (University of Oxford) suggested, however, that the difference may be real. He proposed that the hippocampal changes result in a dissociation between levels of processing. For example in a simple associational task, the human subject cannot talk about what he has learned to associate even though the associational learning is intact. Presumably, animals show no memory deficit because they lack the different levels and communication between levels of processing does not

occur. Which, if either, of these conjectures is correct remains to be seen. In any case, the concern with the attempt to integrate the human and non-human literature is a most important aspect of the problem of species differences and it is gratifying to see so much concern with it at present. □

Sociology of astronomical innovation

from David W. Hughes

SOCIOLOGY is a subject usually omitted from the degree courses of science and engineering students. They are apparently missing a lot; the fascination of the discipline is ably illustrated by a recent paper in the *Quarterly Journal of the Royal Astronomical Society* (18, 326; 1977) by David Edge of the Science Studies Unit, University of Edinburgh.

Edge applies himself to the problems of innovation—the processes of scientific discovery, the invention and introduction of new theories—and he discusses the ways in which astronomy compares and contrasts with other sciences.

Thomas S. Kuhn (*Sociology of Science*, Penguin Books, 1972) has asserted that the general run of scientific activity mainly consists of attempts to force nature into the conceptual boxes supplied by professional education. The scientist is busily accumulating systematically related knowledge within established areas, he is the objective, open-minded searcher after truth, the explorer of nature, the person who rejects prejudice at the threshold of his laboratory. During his education the scientist acquires a set of standards and a collection of mental tools and manual techniques which he can subsequently deploy in his own creative work. He is a puzzle-solver rather like a chess player. Education simply provides him with the rules of the game being played at the moment, initiating him into a pre-established problem-solving tradition without inviting him or equipping him to evaluate that tradition.

Much research is fettered by preconceived convictions and seems to demand a deep commitment to the *status quo*. A belief in the probable success of a venture is obviously an

important motivating factor. Very few scientists would design and build elaborate special-purpose apparatus or would spend months trying to solve a particular differential equation without a quite firm guarantee that their efforts had a high probability of success and would lead to publications and increased status amongst their scientific peer group. The mature scientist can anticipate with considerable precision the sort of result his research should lead to. Knowing what to expect he is then in the ideal position to recognise the anomalous event.

Because gremlins and temporary faults crop up in the large majority of research projects a new discovery often only results when the failure stubbornly refuses to go away. The resolutions of these failures often bring accepted theories and experimental techniques into question thus making the scientific discoverer a controversial figure, a perpetrator of revolutionary thoughts and a swimmer against the normal tides of scientific conservatism.

Very few scientific innovations are made simply by extrapolating from the known. Most are accidental. However, discoveries are not just lying around ready to be tripped over by the aimless wanderer. A high degree of scientific skill is required to discriminate between the key to a new discovery and mere system (or brain) failure.

David Edge has paid special attention to innovations in modern astronomy. His first point is that the large majority of the innovations were not made by astronomers at all but by people who are marginal to the profession. For example, the pioneer British radioastronomers were all physicists, most of them working on applied research. Interestingly the astronomical community at the time tended to ignore the discoveries, and it was many years before a single astronomer changed his experimental strategy and adopted the new radio technique.

The mobility of physicists also seems to be a crucial factor in astronomical innovation. Their experimental competence enabled them to produce results in, for example, the radio, radar, infrared and X-ray fields for an astronomical audience who were not so equipped. Also physicists were not fettered by the stereotype view of the stars and the Universe inculcated into the minds of the professional astronomers. Again innovators seem to thrive if they are one of a large group of scientists (a university department for example) which can provide support for the push into the unknown.

Most astronomical discoveries have been serendipitous, a chance happening in the pursuit of something else. Far too infrequently did discovery come from

David W. Hughes is a lecturer in the Department of Physics, University of Sheffield.

the logical progression of hypotheses, the prediction of a possible new kind of observation, the design, construction and the use of an apparatus to search for the predicted phenomenon and the eventual success, the discovery. In recent times only the discovery of the 21-cm hydrogen line fits this idealistic progression.

A more controversial point in Edge's paper concerns the reception of innovation by scientists. In some disciplines it seems that innovators are treated with apathy and hostility, forced to organise their own societies and journals, mainly because it was thought that the innovation tended to devalue the importance of the hard won skills and competence of established practitioners. Here astronomy seems to be anomalous, most innovators being happily supported and encouraged. Maybe this is because the astronomical innovators are not competing for scarce research resources against members of the established discipline. The pioneers of radioastronomy, for example, were supported by physics and engineering groups.

The final point concerns the strategy of a scientist when faced with a range

of options for future research. To undertake an obvious experiment is to risk outright competition with other workers and possible loss of priority. Attempting a risky or speculative experiment, however, courts failure and also lessens enormously the audience which can appreciate its significance. Most scientists aim for the middle course, trying to prevent duplication and direct competition and trying to ensure success. Innovation, however, opens up a new era into which researchers rush, thus leading to a brief spell of outright competition and its concomitant secrecy.

Edge's paper helps lay to rest the scientists' impression of sociologists as a happy band rambling through science and occasionally stumbling on the obvious with shrieks of amazement. Does an understanding of sociology help the individual scientist? David Edge parries this question by answering that "if you want the (scientific) game to go better, then it is surely necessary to be clear about what kind of game it is". So we may conclude that the sociology of this subject is important, is useful, and should be more widely available to the scientific student. □

kaemic cells were lightly fixed with glutaraldehyde; these were then used to immunise mice, and subsequently to assay antibody binding activity. When the spleens from immune mice were chopped into fragments and placed in microwell cultures, the antibody produced from each fragment could be assayed and from other studies it has been shown that under appropriate conditions each culture well contained one or fewer antibody-producing clones. The second key point of technique was the use of an iodinated rabbit anti-mouse immunoglobulin probe to detect antibody binding to the glutaraldehyde-fixed target cells. Under optimal conditions of spleen fragments culture and microassays for antibody binding, it was possible to obtain sufficient antibody from a single culture well to perform 2,000 assays. In practical terms it means that this technique can provide tumour-specific antibody (by selecting the appropriate culture well) which is tailored to suit the requirements of an individual patient, and in sufficient amounts to monitor accurately the numbers of leukaemic tumour cells during the course of therapy. In short, this technique could provide a major step forward in the management of tumours where chemotherapy is effective but must be closely regulated according to the tumour load.

Serological analysis of human melanoma antigens using autologous sera and cultured melanoma cells from tumour-bearing patients has revealed a variety of antigenic specificities (A. Deleo, Sloan-Kettering). A similar conclusion was reached by S. Ferrone (Scripps Clinic) who tested sera from melanoma patients against a panel of five cultured melanoma cell lines. In both studies there was no evidence of a common tumour-specific antigen as defined by patient sera. However, R. Reisfeld (Scripps Clinic) has shown that a single glycoprotein linked to β_2 -microglobulin can be shown to carry melanoma-specific antigens as defined by a heterologous rabbit antiserum. Putting the available data together, the tentative suggestion emerged that while one, or a few, molecules may carry several antigenic determinants which are tumour specific, there is substantial variation between individuals in the particular constellation of antigens present. In fact one wonders if the HLA system, in which three closely related molecular species carry a cluster of antigenic determinants which vary from one individual to the next, may be an important clue to introducing some order into this field. However, in the absence of genetics, improved chemistry is required to separate these related molecules, and improved serology to elucidate the relationships. □

Analysing tumour antigens

from Rod Langman

The Armand Hammer Cancer Workshop on Tumour Antigens was held at The Salk Institute, San Diego, on 26-29 September, 1977.

A SMALL group representing a wide range of interests met to discuss various aspects of tumour antigens. Classical serological techniques have provided the backbone of current knowledge, but as finer distinctions become necessary the limits of conventional technology in raising and absorbing antisera are being approached. This point was particularly well made during the discussion of chemically-induced tumour antigens. For example, A. Deleo (Sloan-Kettering) used a methyl cholanthrene-induced tumour of Balb/c mice (Meth-A), which had no detectable C-type virus antigen expression, to immunise syngeneic and semi-syngeneic mice. He found that what should be tumour-specific antisera had high levels of nonspecific activity as assayed on a wide range of normal and tumour tissues. These antisera were apparently loaded with antibody against C-type

viral antigens which was produced when, under the stress of immunisation, endogenous C-type virus was induced. Despite extensive absorption the residual tumour-specific antibody still showed unexplained cross reactions that could not be further analysed. H. Festenstein (London Hospital) reported that the methyl cholanthrene-induced P815 tumour has apparent alterations in the H-2 alloantigens, as detected by standard reference antisera. From this and a number of similar observations it was proposed that tumorigenesis may involve modulated expression of H-2 alloantigens. While this interpretation was not widely accepted at the workshop, no competing explanation could be offered. Without better defined monospecific antisera it seems that antigens on chemically-induced tumours will remain elusive.

Although an obvious approach to preparing monospecific antibody, the Milstein-Galfre myeloma hybridisation technique has not yet been applied to tumour antigens. However, R. Levy (Stanford University) did introduce a variant of this idea when he described his adaptation of the Klinman spleen-fragment method for preparing antibody to human leukaemic cells. First, large numbers of the patient's leu-

Isoscalar breathing mode states identified in ^{144}Sm and ^{208}Pb

from P. E. Hodgson

OVER the past few years many collective multipole excited states of nuclei have been found, mainly by inelastic scattering measurements. The energy spectra of the inelastically-scattered particles show separate peaks at the higher energies due to the excitation of the low-lying states and a broad peak at lower energy due to the excitation of multipole resonances. The multipolarity of the resonance can usually be found by studying the angular distribution of the resonance peak, and comparing it with the distribution calculated from a model of the resonant state with various assumed multipolarities. In this way much has been learnt about the giant quadrupole resonance, but so far it has proved difficult to identify the monopole or breathing-mode state. This is called the breathing mode because it corresponds to the nucleus changing size but not shape, and this shows that its energy is closely related to the nuclear incompressibility.

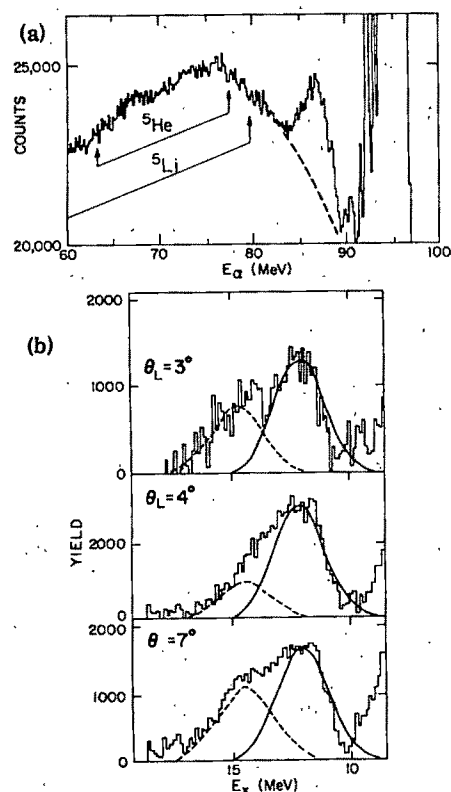

Fig. 1 Energy spectra of the α particles inelastically scattered from ^{208}Pb (a) and ^{144}Sm (b) showing the analysis of the giant resonances into two peaks.

In a recent experiment, Youngblood and colleagues of Texas A&M University have found that inelastic α -particle scattering at forward angles provides clear evidence for the breathing-mode excitation in ^{144}Sm and ^{208}Pb (*Phys. Rev. Lett.* **39**, 1188; 1977). In their earlier work with 97 and 115 MeV α particles they had found that the giant resonance peak has two components, but both had the same angular distribution and were assigned to the giant quadrupole resonance.

The new experiments were made with 98 MeV α particles, and measurements were made at much smaller angles than before, between 3° and 8° to the incident beam. Some of their results are shown in Fig. 1, together with the analysis of the giant resonance peaks into two components. The angular distributions of the two peaks are shown in Fig. 2, and it is clear that they are very different, especially around 4° . The multipolarities of the resonances were found by making calculations of the angular distributions assuming that the states are monopole, isovector dipole, quadrupole and hexadecapole, corresponding to $L = 0, 1, 2$ and 4 respectively. It is clear in each case that the data for the component at the lower energy is well fitted by the quadrupole curve and for the component at the higher energy by the monopole curve in each case. In particular, the predicted signature of the monopole state, a sharp minimum around 4° , is very clear in the data for the excitation to the higher energy for both nuclei, while it is absent in the data for the lower energy excitation.

The giant multipole excitations should satisfy sum rules, which means that the integrated strength of all their components should add to a value that can be calculated from the theory of the excitations. In the present experiments, it is found that all four resonances satisfy the energy-weighted sum rule to within the uncertainties of the analysis. This is a valuable confirmation of the correctness of the assignments.

The results for the breathing-mode excitation energies are in good agreement with previous experimental work, and with the recent theoretical estimates. According to the liquid drop model, the monopole excitation energy is related to the nuclear incompressibility K by

$$E_0 = \pi/3 R (\hbar^2 K/m)^{1/2}$$

where R is the nuclear radius and m the nucleon mass. The excitation energies 13.7 MeV for ^{208}Pb and

Fig. 2 Angular distributions of the two components of the giant resonance peaks in ^{144}Sm and ^{208}Pb compared with distorted wave calculations assuming various values of the multipolarity L .

15.1 MeV for ^{144}Sm give values of 208 and 197 MeV for K respectively, which are consistent with other theoretical estimates. \square

A hundred years ago

MR. STANLEY will probably arrive in England this week. He has been received with enthusiasm at Rome, Marseilles, and Paris. The Chamber of Commerce and the Geographical Society of Marseilles presented Mr. Stanley with medals. No doubt our own Geographical Society will take the lead in the warm reception which will certainly be accorded in this country to one of the foremost of explorers.

THE wolves in Eastern France have become unusually bold during this winter, and reports are constantly received of their depredations in various parts of the country. In one instance a letter-carrier was driven back by them from his regular route.

From *Nature* 17, 17 January, 232; 1878.

P. E. Hodgson is a lecturer in Nuclear Physics at the University of Oxford.

review article

Why has Regge pole theory survived?

Elliot Leader*

In spite of a very mixed record of success and failure, Regge theory, in which the notion of complex angular momentum is introduced into quantum mechanics still lives on. What has dissuaded physicists from discarding it, and what is our present assessment of the theory?

PHILOSOPHERS of science, who ponder the survival and demise of scientific theories, would do well to test their ideas against the progress of Regge Pole Theory since its inception in 1959.

Tullio Regge's great imaginative leap, the introduction of the notion of a complex angular momentum in non-relativistic quantum mechanics¹, might have ended in oblivion, weighed down by its overpowering mathematical sophistry and rigour, had not S. Mandelstam, seizing upon its crucial element and casting off the enveloping mathematical shroud, demonstrated a direct and striking consequence in the behaviour of high-energy elementary particle collision processes (Mandelstam did not publish this work, but his rôle is acknowledged in many papers).

Thereupon Regge theory really took fire and blazed through the ranks. In no time at all 'Regge pole' (pole in the mathematical sense) had become a household expression. Indeed there is the story of a party at which the charming wife of an American physicist, on being introduced to 'Regge', exclaimed: "Ah Mr Pole! I'm so pleased to meet you at last."

What is it that Regge did? What were the consequences? Where does the matter now stand?

Much of elementary particle physics is concerned with the scattering amplitude F , a function which controls the probable outcome of a collision between two particles. In the simplest case F depends only upon the energy of the collision E and upon the angle θ through which one of the particles is deflected. The behaviour of $F(E, \theta)$ reflects, albeit in a complicated way, the nature of the fundamental dynamical forces acting between the particles; hence its importance.

In ordinary quantum mechanics, where the forces are known, $F(E, \theta)$ is deduced by solving the Schrödinger Equation. Traditionally it was always simplest not to aim for $F(E, \theta)$ itself, but rather to study the collision at a fixed value of the angular momentum l . The forbidding Schrödinger Equation breaks up into a set of much simpler equations, one for each value of l ; l of course, being restricted to positive integer multiples of Planck's constant, as it must be in quantum mechanics. Thereby one obtains a set of amplitudes $f_l(E)$, $l = 0, 1, 2, \dots$, from which it is possible to construct $F(E, \theta)$ itself.

It has long been known that there are certain advantages in adopting the fiction that the energy E can be a complex number, that is, have both real and imaginary parts, and in considering each $f_l(E)$ as a function of the complex variable E (refs 2,3). The remarkable consequence of this bizarre strategy is the following. Suppose that the two particles whose collision is under study are capable of binding together to form a stable bound state, say with angular momentum L and (negative) energy E_B . Then the L th one of the above functions, that is, $f_L(E)$ will be found to have a 'pole' at the negative value $E = E_B$, that is, a simple infinity of the form $1/(E - E_B)$. The continuation of the energy E from its real positive

physical values to complex and negative values has unified the consideration of scattering processes and the existence of bound states.

With hindsight it is obvious that the next, even more bizarre, step ought to have been to try to allow the angular momentum l to take on non-integer, and indeed, complex values. But between the generalisation of the smoothly varying energy E to complex values and a like extension of the variable l , which physically took on only the values $0, 1, 2, \dots$, lay a great psychological barrier. Indeed 33 years were to pass before Regge's brilliant papers laid down the foundation of the theory of complex angular momentum.

Of course, Regge did not complexify for the sake of complexification. It is probable that he saw the introduction of complex l principally as an aid toward proving certain mathematical properties of the scattering amplitude that he had been trying to establish. The harvest was richer than expected.

First there emerged a new way of classifying stable bound states and resonances (quasi-stable states) into families. Instead of focussing separately on a bound state with a given angular momentum, say $l = 0$ with energy E_0 , and then upon one with angular momentum $l = 1$ with energy E_1 , and so on, one now focussed on a single object, the 'trajectory function' $\alpha(E)$ with the property that if a particular value of E should cause $\alpha(E)$ to equal a positive integer, say L , then a bound state would exist at that energy E and with angular momentum $l = L$. Thus in the above example the bound states would correspond to finding $\alpha(E_0) = 0$, $\alpha(E_1) = 1$, and so on. The curve $\alpha(E)$ against E signals the existence of bound states or resonances if and when it passes through integer values.

The bound states at energies E_0 , E_1 , and the resonance at E_2 (positive energy) are united into a new kind of family characterised by their trajectory function.

Second, it was found that just as $f_L(E)$ has a pole, that is, is infinite at the energy E for which a bound state of angular momentum $l = L$ exists, so now $f(l, E)$ has a pole, a 'Regge pole' whenever E is such that $\alpha(E)$ equals the value of l under consideration. The Regge pole coincides with the physical bound

*Westfield College, University of London.

states or resonances when this value happens to be an integer.

Third, it was established that in the quite unphysical region of very large $\cos \theta$ (that is, $\cos \theta \gg 1$) the scattering amplitude is proportional to $(\cos \theta)^{\alpha(E)}$. In some mysterious way the Regge trajectory function $\alpha(E)$, so intimately linked to the properties of the bound states, is also responsible for controlling the growth of the scattering amplitude in the weird region of large $\cos \theta$.

This, in the broadest of terms, was the achievement of Regge. Whatever he proved is unquestionably true and will remain so as long as quantum mechanics holds sway. Indeed Regge theory has been included in good undergraduate text books for more than a decade.

Beautiful though this all is, it is very heavy going mathematically and might have remained undigested for a long time had not Mandelstam emphasised that in the real world of relativistic physics the quite meaningless limit of large $\cos \theta$ in the reaction $A + B \rightarrow A + B$ is closely related to the physically sensible, and exceedingly interesting, limit of high energy in the related reaction $A + \bar{A} \rightarrow B + \bar{B}$ involving the antiparticles \bar{A} , \bar{B} of A and B .

The full story is technical and difficult, but what emerges is remarkably simple and quite dramatic: the behaviour of the scattering process $A + B \rightarrow A + B$ at very high energies E is proportional to the energy raised to the power $\alpha(t)$ that is, $E^{\alpha(t)}$, where α is the Regge trajectory connected with the bound states and resonances of the $A\bar{A}$ or $B\bar{B}$ systems. (t is the square of the 'momentum transfer' in the scattering—roughly $(E\theta)^2$).

Two points are noteworthy: that there is such a close link between high energy behaviour and the properties of the bound states and resonances, and that the behaviour thus predicted at high energy, in which the power to which E is raised depends upon t (and therefore upon θ), is quite in contrast with what had been expected.

Like theologians of old taunted by the threat of a heliocentric solar system, the experimentalist rushed forth to destroy the theory. Amazingly, the first results from CERN in 1961 seemed to support the theory. Proton-proton scattering was changing with energy as predicted. (The diffraction peak was shrinking.) Enraged, the experimentalists tried harder. (There was the famous slide, shown at a conference in 1963, in which a certain experimentalist appears imperiously surveying his apparatus with one raised foot thrust firmly on top of a large dark rectangular box—said to be the coffin of Regge theory.) Of no avail; the physical world seemed to be in tune with Regge, and remained so for some time.

Then the reaction set in. The experimentalists, exploring all the different reactions they could think of, discovered behaviour that was sometimes not quite what was expected. The theorists, probing the intricacies of the argument, found all sorts of problems in going from the non-relativistic to the relativistic situation. Hundreds of papers were written, spawning a rich and exotic vocabulary. Trajectories could bear 'daughters'; trajectories might 'conspire' together; 'ghost-killing' mechanisms would have to operate at certain 'nonsense' points. And so on.

Many of these points have never been resolved fully, but what emerges as the main difficulty in Regge theory can be understood heuristically as follows.

Quantum field theory taught us, long ago, to regard scattering processes as 'mediated' by the exchange of 'virtual' particle, with some well-defined spin, a π -meson say, with zero spin,

and bequeathed to us the impossible task of summing up the effects of exchanging these virtual particles in all possible ways.

The expression given by Regge Theory, drawn symbolically as

miraculously represents, at high energies, the sum of a huge subset of these diagrams, and can be thought of as representing the exchange of a composite object a 'Reggeon' with variable spin—the rôle of the spin being played by the ubiquitous $\alpha(t)$.

But though infinitely large, this subset does not, alas, exhaust all the diagrams, and we are forced to grapple with multi-Reggeon exchange diagrams such as

The theory becomes difficult and subtle—a new form of field theory—but at least one relieved of some of the worst idiosyncrasies of ordinary field theory. For example, in ordinary field theory it is impossible to allow the exchange of a particle whose spin is greater than one unit, because doing so triggers the appearance of unmanageable infinities in the calculations. But Reggeons with arbitrarily high spin can be exchanged with equanimity.

Reliable results for diagrams with multi-Reggeon exchange are hard to come by. It does seem, though, that adding in the results of multi-Reggeon exchange gives answers substantially different from the single Regge pole results. If so, what on earth does the good agreement between some experiments and single Regge pole exchange mean?

That is the present conundrum. Why do some experiments support Regge poles? Why do others disagree? And is the disagreement in a direction that could be explained by multi-Reggeon exchange?

In the past few years there have been two shifts of emphasis in the experimental work.

(1) Improved techniques of detection and the availability of more intense beams of elementary particles from the new accelerators have made it possible to study more refined aspects of collision processes. Rather than simply asking with what frequency particle C emerges at angle θ in the reaction $A + B \rightarrow C + D$, one can now ask also about its 'polarisation' (the direction of its spin), or even about the correlation between the direction of its spin and that of D .

Regge pole theory makes very precise predictions for these measurements—and they are generally wrong. A marvellous example is the reaction

in which the colliding positively charged proton and negatively charged π -meson effectively swap electric charges, emerging as an electrically neutral π -meson and neutron. It can be demonstrated quite rigorously that one, and only one, kind of Reggeon can be exchanged in this process. Thus the usual complication arising from the adding of the effects of several Reggeons is absent and the predictions of pure Regge pole theory are laid bare, open, one might have believed, to the ultimate judgement.

The measured angular distribution of the emerging particles and the manner in which this changes with energy provide a brilliant success for the theory. Even the shape of the angular distribution (see Fig. 1) with its changing sharp minimum is understood as a consequence of the structure of the theory. (The trajectory involved is that of the ρ -meson family and the point at which the minimum occurs corresponds to the value of t at which

$\alpha_p(t) = 0$). But the spin of the neutron, predicted quite firmly to be orientated randomly, with no specially preferred directions, has now been found to point predominantly in one particular direction (it is polarised) thus dealing a grievous blow to the theory.

Another example of great interest is the pair of reactions

$$\pi^+ p \rightarrow \pi^+ p$$

$$\pi^- p \rightarrow \pi^- p$$

involving the collision of π -mesons of positive or negative electric charge with protons. For reasonably small angles of scatter one expects little difference between the two reactions, and this is confirmed experimentally, but for large angles of scatter (close to 'backward' scattering) Regge theory predicts significantly disparate behaviour. The reason is simple. In the reaction $\pi^- p \rightarrow \pi^- p$, at large angles of scatter, the only Regge pole of importance is that belonging to the family of nucleon resonances usually labelled Δ (the first member is the spin 3/2, isotopic-spin 3/2 resonance with mass 1,236 MeV), so the dependence upon energy in backward $\pi^- p \rightarrow \pi^- p$ is proportional to E raised to the power α_Δ . On the contrary, in the reaction $\pi^+ p \rightarrow \pi^+ p$ at backward angles, two Regge poles play a part, one belonging to the Δ family and the other to the family of the nucleon itself (labelled N), and their effects must be added. Are they equally important? The shape of the angular distribution in $\pi^+ p \rightarrow \pi^+ p$ (see Fig. 2), with its very sharp minimum close to point of completely backward scattering ($\theta = 180^\circ$), would emerge naturally from the theory if the N Regge pole dominated. (The dip would just correspond to the point at which $\alpha_N(t) = 0$). Our conclusion: at medium energies, where the processes have so far been measured, the N Regge pole dominates, and since it only

Fig. 1 The angular distribution in $\pi^- p \rightarrow \pi^0 n$ at several energies⁴, ∇ , CERN, 1968 5 GeV; Δ , CERN, 1965 10 GeV; \blacksquare , HEP, 1974 21 GeV; \circ , Fermilab, 1974 40.6 GeV; \bullet , Fermilab, 1974 101 GeV; \square , Fermilab, 1974 200 GeV.

Fig. 2 The angular distributions for $\pi^- p \rightarrow \pi^- p$ (---) and $\pi^+ p \rightarrow \pi^+ p$ (—) near the backward direction (eye fits)⁵.

contributes to one of the reactions, that is, to $\pi^+ p \rightarrow \pi^+ p$, we have a natural explanation for the striking difference between the angular distributions of the two reactions (Fig. 2).

But now comes the rub. From the properties of the two families of particles, N and Δ , we know that α_Δ must be numerically greater than α_N . Thus although at present energies the N contribution dominates in $\pi^+ p \rightarrow \pi^+ p$ this cannot continue to be true at higher energies. For the Δ contribution is growing like E^{α_Δ} , compared with E^{α_N} for the N, and is bound to overhaul the N and eventually dominate at very high energies.

We thus have a dramatic prediction for very high energies. Both reactions $\pi^+ p \rightarrow \pi^+ p$ and $\pi^- p \rightarrow \pi^- p$ will be dominantly controlled by the same Regge pole Δ . Their angular distributions, so dissimilar at medium energies, will then look alike, and will take on the shape at present shown by $\pi^- p \rightarrow \pi^- p$.

A splendid and challenging prediction! But preliminary results at fairly high energies (about 70 GeV) show no change at all. The $\pi^+ p$ angular distribution is just as sharp and spiky as it ever was. Very careful measurements are planned at Fermilab at energies of 100–200 GeV. Their outcome is eagerly awaited.

As a last and most mysterious example consider neutron-proton collisions in which the neutron bounces back at very large angles. Although the experiments are difficult (because it is hard to know exactly how many neutrons are arriving per second in one's beam) it does seem to be established that the energy dependence in this reaction is most peculiar. It starts off at low and medium energies behaving as if it was controlled by the trajectory α_π belonging to the Regge family of the π -meson. As α_π is approximately equal to zero, E^{α_π} gives hardly any change at all as the energy increases. But suddenly, at energies in the region of 60 GeV, it begins to grow. Now some growth with energy is not at all surprising. In fact, it is predicted, because the trajectory α_ρ of the ρ -meson Regge family, should also play a part, and its numerical value is about $\frac{1}{2}$, yielding a contribution increasing like $E^{1/2}$. But the growth discovered experimentally seems to be far more rapid; some would even claim it proportional to E itself.

If this were to be substantiated it would really upset the apple-cart—for the number one, to which power it is claimed E is raised, is in Regge theory somewhat sacrosanct. It is the attribute only of that mysterious trajectory, the 'Pomeron', which so far as we know, is not connected with any family of particles or resonances, and which possesses the virgin properties of the vacuum itself—no electric charge, no baryon number, no isotopic spin, no strangeness.

But the Pomeron's rôle is limited to 'diffractive' processes; elastic reactions like $pp \rightarrow pp$ or $np \rightarrow np$ in which the projectile is scattered through a very tiny angle. In our example of large angle or backward scattering it is impossible to exchange a Pomeron. Whatever we exchange must be electrically charged and have a non-zero value of isotopic spin.

What should we conclude? Are the experiments wrong? Or if they are correct, are we discovering the existence of pretenders to the Pomeron throne? Is there perhaps a family of privileged Regge poles, with trajectories like the Pomeron's, but with different sets of charges, isotopic-spins and so on? (We have, in a moment of fantasy, already speculated upon the existence of such objects—and called them 'Odderons'⁶). Or, finally, is the unexpected energy dependence simply a signal of the failure of Regge pole theory?

(2) The existence of very high energy beams of particles has stimulated interest in reactions in which many particles are produced in the collision:

It is not generally possible to identify and analyse the properties of all the particles emerging, so, often, attention is focussed upon just one of them. (Measurements of this type are rather inappropriately referred to as 'inclusive' experiments.) A very clever argument of A. Mueller⁷ shows that many of the properties of inclusive experiments ought to be controlled by the same Regge poles that are active in the simpler reactions we were considering earlier. Many measurements, principally of the angle and momentum of one of the emerging particles in inclusive experiments, have agreed nicely with the predictions, and have yielded Regge trajectories in good agreement with those determined from simple scattering processes. But recently, a new phase in the experiments, in which the spin of the particle is also measured, has begun to provide some surprising results in contradiction with Regge pole theory.

The best example is probably one in which protons collide with a Beryllium target at 300 GeV to produce neutral lambda particles (Λ^0) plus much debris that is ignored:

Normally it is exceedingly difficult to determine the direction of a fast particle's spin, but it is a peculiar favour of Nature that when the Λ^0 , which is unstable, decays into a proton and a π^-

meson, one can determine the spin-direction which the Λ^0 had from an elementary study of the angles of emergence of these decay products. (The Λ^0 is said to be 'self-analysing'.) According to Regge pole theory the Λ^0 should not be polarised. Experimentally, however, there is a definite favouring of one particular direction for the spin.

Where, finally, do we stand?

As regards Regge's own contribution, the introduction of the concept of complex angular momentum into quantum mechanics, that, as we have said, is inviolate. But the generalisations to the relativistic domain of elementary particle physics are fraught with difficulty and have a mixed record of success and failure. Many indeed are the predictions of angular distributions and their change with energy that have been confirmed experimentally, but many too are the cases of disagreement.

Given this state of affairs, is it conceivable that Regge pole theory is correct? In its simplest, naive form, with the exchange of single Reggeons, there is no hope. In its broader guise, with multi-Reggeon exchange, we simply do not know the answer. Sometimes it looks as if results are in the right direction but the calculations are too difficult, and any confrontation between experiment and these calculations could just as well reflect inaccuracy in our approximations as some basic fault of the theory.

Strangely though, despite these uncertainties, and even if the theory may be wrong, the language of the theory is likely to survive for a long time to come. For, stripped of all its details, Regge pole theory does focus upon a link between the behaviour of scattering and the quantum numbers of the 'object' that can be exchanged. And this, at a qualitative level, does seem to be a correct and useful concept. But the elucidation of the detailed dynamical properties of this 'object' will have to await a new Regge.

Reflection of X rays by neutron star surfaces

R. Lenzen & J. Trümper

Max-Planck-Institut für Physik und Astrophysik, Institut für extraterrestrische Physik, D-8046 Garching, FRG

A neutron-star surface should act as a good reflector for photons up to hard X-ray energies, due to the high density of the magnetic surface matter. Reflectivities are high, especially in spectral bands above the plasma and cyclotron frequencies depending on the photon polarisation. X-ray reflection may be important for the beaming of the binary neutron star Her X-1 and similar objects.

X RAYS are reflected under glancing angles by flat surfaces of condensed matter. This phenomenon is based on the fact that, for X-ray energies away from absorption edges the electrons can be considered as free particles such that the photons interact with them coherently. At frequencies ω larger than the plasma fre-

quency $\omega_p = (4\pi e^2 n_e / m_e)^{1/2}$, the refractive index $n = \{1 - \omega_p^2 / \omega^2\}^{1/2}$ is real and smaller than unity. Consequently, total external reflection occurs at glancing angles $\alpha < \alpha_c = \cos^{-1} n$. For terrestrial materials $n_e \sim 10^{24} \text{ cm}^{-3}$ and α_c is $\sim 2^\circ$ for $\sim 1 \text{ keV}$ photons.

According to current concepts (see, for example, ref. 1) a neutron star surface consists of a solid or liquid magnetic polymer. With respect to its reflective properties two radical changes occur in comparison with terrestrial matter. First, the surface electron density is $\propto B^{6/5}$ and will be of the order $\sim 10^{28} \text{ cm}^{-3}$ for $B \sim 10^{12} \text{ G}$ fields². This leads to a plasma frequency which is ~ 100 times larger than for normal matter. Consequently, glancing reflection should occur up to $\sim 100 \text{ keV}$ at 2° , or up to much larger angles at lower energies.

Second, the electron plasma is highly anisotropic since the

electron can move freely only along the magnetic field lines while their motion is quantised in the transverse direction. Consequently, the refractive and reflective properties of the surface will strongly depend on the magnetic field orientation and on the electron cyclotron frequency $\omega_B = eB/m_e c$.

Both effects depend crucially on the surface magnetic field strength, which is now known³ with some precision for the neutron star Her X-1 ($\sim 5 \times 10^{12}$ G). This fact and the possible effects of X-ray reflection on the beaming of this or other X-ray sources led us to investigate this problem quantitatively. Unfortunately, nothing is known about the macroscopic surface structure of neutron stars. But, it seems reasonable to assume that it is smooth enough to exhibit at least some mirror qualities.

We calculate here the X-ray reflectivity of a neutron star surface as function of photon energy, polarisation, and angle of incidence under idealised conditions. We also discuss possible deviations expected to occur in the case of real neutron star surfaces and summarise some expected observational effects which may have a role for systems like Her X-1.

X-ray reflection at a neutron star surface

We assume a plane surface which represents a sharp transition from vacuum to the high density surface matter. The magnetic field is orientated perpendicular to the surface. The latter will be a good approximation in the vicinity of the accretion column at a neutron-star magnetic pole. As already discussed, the X-ray optical properties of the surface will depend on the electron plasma frequency

$$\hbar\omega_p = (4\pi e^2 n_e / m_e)^{1/2} \hbar \quad (1)$$

and on the electron cyclotron frequency

$$\hbar\omega_B = eB/m_e c \hbar = 11.6 \times B_{12} \text{ keV} \quad (2)$$

The total number density of electrons can be calculated from the nuclei density of the condensed magnetic matter², which results in

$$n_e = 1.24 \times 10^{27} Z_{26}^{2/5} B_{12}^{6/5} \text{ cm}^{-3} \quad (3)$$

Assuming that the surface consists of iron we get for the plasma frequency

$$\hbar\omega_p = 1.45 \times B_{12}^{3/5} \text{ (keV)} \quad (4)$$

We neglect here the atomic binding energies of the electrons which is justified by the fact that for $B \sim 5 \times 10^{12}$ G and iron nuclei most electrons have binding energies smaller ~ 2 keV (W. Hillebrandt, personal communication).

In order to calculate reflectivities we follow the classical approach and use the boundary conditions which must be satisfied on the surface by the electromagnetic fields (see ref. 4). Besides the incident and reflected waves we have to consider two

refracted waves as two modes of propagation, the ordinary and the extraordinary one, exist in the magnetised plasma.

Figure 1 depicts the coordinate system and the notation used. The magnetic field is orientated perpendicular to the surface which is given by the plane $z = 0$, $y = 0$ is the plane of incidence. We neglect the effects of vacuum birefringence in a strong magnetic field^{5,6} and assume an index of refraction $n_0 = 1$ above the surface. This is justified because for a 10^{12} G field the deviations from unity are of the order 10^{-5} . Below the surface the dielectric properties are described by a tensor ϵ . The different waves are characterised by their electric vectors E and wave vector k .

We first consider the properties of the two refracted waves. The refraction indices for the ordinary and extraordinary mode of propagation are given by the dispersion relation (refs 7 and 8):

$$\begin{bmatrix} S - n_m^2 \cos^2 r_m & -iD & -n_m^2 \sin r_m \cos r_m \\ iD & S - n_m^2 & 0 \\ -n_m^2 \sin r_m \cos r_m & 0 & P - n_m^2 \sin^2 r_m \end{bmatrix} \begin{bmatrix} E_{xm} \\ E_{ym} \\ E_{zm} \end{bmatrix} = 0 \quad (5)$$

$$\text{with } R = 1 - \frac{\omega_p^2}{\omega^2} \frac{\omega}{\omega - \omega_B + i\omega_D}$$

$$L = 1 - \frac{\omega_p^2}{\omega^2} \frac{\omega}{\omega + \omega_B + i\omega_D}$$

$$P = 1 - \frac{\omega_p^2}{\omega^2} \frac{\omega}{\omega + i\omega_D}$$

$$S = \frac{R+L}{2}$$

$$D = \frac{R-L}{2}$$

where ω_p , ω_B , and ω_D are the plasma frequency, the cyclotron frequency and the damping frequency, respectively, and the index $m = 1, 2$ describes the ordinary and extraordinary mode. From this dispersion relation we derive the following amplitude ratios:

$$\frac{E'_{mx}}{E'_{mz}} = \frac{P - n_m^2 \sin^2 r_m}{n_m^2 \sin r_m \cos r_m} = \alpha_m \quad (6)$$

$$\frac{E'_{my}}{E'_{mz}} = \frac{-iD \alpha_m}{S - n_m^2} = \beta_m \quad (7)$$

and, as the determinant must vanish, the quartic equation for the two refractive indices:

$$An_m^4 - Bn_m^2 + C = 0 \quad (8)$$

with $A = S \sin^2 r_m + P \cos^2 r_m$

$$B = RL \sin^2 r_m + PS \cdot (1 + \cos^2 r_m)$$

$$C = PRL$$

For propagation modes, both the ordinary and the extraordinary ones, refraction is described by Snell's law

$$n_m = \sin i / \sin r_m \quad (9)$$

in which n_m implicitly depends on r_m .

The angle of refraction r_m can be calculated if we replace n_m in (8) by (9) and solve for $\sin r_m$. Inserting these values into (6) and (7) we find the amplitude ratios α_m and β_m of the electric field components below the surface.

In order to determine the electric field components of the reflected wave we use the boundary conditions at the surface which read in the present case:

Fig. 1 The propagation vectors for refraction and reflection at the plane surface.

Fig. 2 X-ray reflectivities as function of photon energy for different polarisations of the incoming photon and grazing angles between 10° and 80°. Plasma frequency, 4 keV; cyclotron frequency, 58 keV; damping frequency, 0.1 keV. *a*, Polarisation parallel to plane of incidence; *b*, polarisation perpendicular to plane of incidence.

$$\left[\mathbf{E} + \mathbf{E}'' - \sum_{m=1}^2 \mathbf{E}'_m \right] \cdot \mathbf{Z}_0 = 0 \quad (10)$$

$$\left[\mathbf{k} \times \mathbf{E} + \mathbf{k}'' \times \mathbf{E}'' - \sum_{m=1}^2 \mathbf{k}_m' \times \mathbf{E}_m' \right] \cdot \mathbf{Z}_0 = 0 \quad (11)$$

$$\left[\mathbf{E} + \mathbf{E}'' - \sum_{m=1}^2 \mathbf{E}'_m \right] \times \mathbf{Z}_0 = 0 \quad (12)$$

$$\left[\mathbf{k} \times \mathbf{E} + \mathbf{k}'' \times \mathbf{E}'' - \sum_{m=1}^2 \mathbf{k}_m' \times \mathbf{E}_m' \right] \times \mathbf{Z}_0 = 0 \quad (13)$$

where \mathbf{Z}_0 is the unit vector in z -direction.

Representing \mathbf{E} and \mathbf{E}'' by their components perpendicular and parallel to the plane of incidence, one gets the linear equations:

$$\begin{bmatrix} E_{\perp} \\ E_{\parallel} \\ E_{\parallel} \\ E_{\parallel} \end{bmatrix} = \begin{bmatrix} \beta_1 & \beta_2 & -1 & 0 \\ \frac{n_1 \cos r_1 \beta_1}{\cos i} & \frac{n_2 \cos r_2 \beta_2}{\cos i} & 1 & 0 \\ \frac{\alpha_1}{\cos i} & \frac{\alpha_2}{\cos i} & 0 & 1 \\ \frac{P}{\sin i} & \frac{P}{\sin i} & 0 & -1 \end{bmatrix} \cdot \begin{bmatrix} E'_{1\perp} \\ E'_{2\perp} \\ E'_{1\parallel} \\ E'_{2\parallel} \end{bmatrix} \quad (14)$$

Inverting this system of linear equations gives the dependence of E_{\parallel} on E . The corresponding reflectivities $|E''|^2/|E|^2$ and $|E'_{\parallel}|^2/|E_{\parallel}|^2$ as a function of photon energy are shown in Figs 2 and 3, where we have replaced the angle of incidence i by the grazing angle $\pi/2 - i$.

For the cyclotron frequency the value measured for Her X-1 (58 keV, ref. 3) is used. The plasma frequency was calculated for

the corresponding magnetic field strength (5.3×10^{12} G) using equation (4), which leads to $\hbar\omega_p \sim 4$ keV. The damping frequency in intense magnetic fields has been treated in ref. 9. It turns out that in the present case $\hbar\omega_D$ is of the order 10 to 100 eV, that is small compared to X-ray photon energies. To improve the legibility of the figures in the vicinity of the resonances we arbitrarily used for our calculations a value $\hbar\omega_D = 100$ eV.

Figures 2 and 3 show that for photons polarised in the plane of incidence the reflectivity is near unity in a spectral band between $\hbar\omega_p$ and a cut-off energy depending on the grazing angle. Total external reflection ($n < 1$) takes place in this region. At the cyclotron frequency a small peak occurs which corresponds to the excitation of the extraordinary mode in the surface.

For photons polarised perpendicular to the plane of incidence one finds substantial reflectivity below the plasma frequency and in a spectral band between $\hbar\omega_B$ and a cut-off energy depending again on the grazing angle. Also in this upper energy band the high reflectivity is due to total external reflection ($n < 1$). We note that both spectral bands in which total external reflection occurs are limited by very steep slopes on both sides. If one plots the reflectivity as function of the grazing angle, as shown in Fig. 4, one finds a steep cut-off behaviour here as well.

Application to Her X-1

According to the generally accepted model for Her X-1, the pulsed X rays originate from hot spots at the magnetic poles on the stellar surface which are heated by the accreted material falling down along the polar field lines. It is clear that a beaming mechanism is required in order to account for the sharpness of the observed 1.24-s X-ray pulses, however, there is no agreement regarding the beaming geometry. The basic possibilities discussed are pencil beams (along the polar field lines) or fan beams (perpendicular to the field lines). We regard the fan beam geometry as the more likely possibility since the radiation most easily escapes sideways from the base of the accretion funnel. In this case part of the radiation will hit the stellar surface where it undergoes reflection, as discussed above. The reflected component should lead to sharp structures in the spectral time variability of the source due to the sharp on-sets and cut-offs in reflectivity as functions of grazing angle and photon energy.

Observations show that the 1.24-s pulsations of Her X-1 are characterised by: a double peak structure at low energies (~ 2 to ~ 20 keV, refs 10, 11); single peaks between ~ 20 keV and

Fig. 3 Same as Fig. 2; grazing angles 4° to 10° .

~ 60 keV, including the cyclotron resonance at ~ 58 keV (ref. 12); and a double peak structure between ~ 60 keV and 90 keV, that is above the cyclotron resonance (ref. 12).

This complex behaviour can be explained by the following simple model. Between 20 and 60 keV one sees the direct, unmodified fan beam which is emitted from the base of the accretion column under a polar angle $\sim \pi/2$. This requires that near pulse maximum the line of sight is approximately at right angles to the polar field lines. In the 2 – 20 keV range and above the cyclotron resonance at 58 keV, an additional reflected beam occurs which has its intensity maximum at $\theta_m < \pi/2$. As the line of sight crosses the reflected beam twice in one rotational period, namely just before and after reaching the fan beam maximum, double pulses are produced which are superimposed on single pulses.

According to Figs 2 and 3 the spectrum of the reflected beam will strongly depend on the polarisation of the incident beam. This polarisation, however, is expected to be zero, as any

polarisation of the X-ray beam emerging from the accretion column will be completely destroyed as the beam propagates through the strong magnetic field near the neutron star due to vacuum birefringence⁶. Therefore, the shape and spectrum of the reflected beam will depend only on the shape and spectrum of the fan beam, and not on its polarisation properties at emission which may be very complex.

Our considerations will not be altered substantially if we drop the assumption of a plane mirror with perpendicular magnetic field made above and consider the spherical polar cap of a neutron star with a dipolar magnetic field. A considerable deterioration of specular reflection, however, will be caused if an atmosphere exists which is dense enough to scatter the photons incoherently before they reach the high density surface. The answer to the question of whether such an atmosphere exists will depend on the cohesive energy of surface matter and on the surface temperatures. At 5×10^{12} G the cohesive energy of the linear chains which form the condensed matter is ~ 8 keV (ref. 2). In the immediate

Fig. 4 X-ray reflectivities as function of grazing angle for different energies and polarisations of the incoming photons. *a*, Polarisation parallel to plane of incidence; *b*, polarisation perpendicular to plane of incidence.

surroundings of the radiating accretion column the surface temperature may be above this value due to heating by the refracted photons and Thomson scattering recoils. Also heat conduction in the stellar material may play a role in this context. One, therefore, expects that up to a certain radial distance from the accretion column the neutron star surface is covered by a dense atmosphere and represents a 'tarnished mirror', reflecting quasi-isotropically by Thomson scattering. Specular reflection will occur in a ring zone between this region and the neutron star horizon as seen from the radiation source.

Finally, the Thomson scattered component may account for the off-pulse emission of Her X-1 which has a spectrum similar to that of the pulsed component. Another source of the diffuse off-pulse component may be the scattering by surface micro-roughness or Bragg reflection by the one-dimensional lattice of the magnetic polymer constituting the surface matter. A more detailed model for the complex spectral variability of Her X-1 will be discussed in a separate paper.

After writing this paper we became aware of ref. 13, which contains an alternative and more general treatment of the electrodynamical problem of 'reflection and refraction of electromagnetic waves on plasma in homogeneous magnetic fields'. This problem has also been discussed in ref. 14 in the context of emissivity of magnetic neutron star surfaces.

Rb-Sr mantle isochrons and variations in the chemistry of Gondwanaland's lithosphere

C. Brooks

S. R. Hart

Department of Earth and Planetary Sciences, Massachusetts Inst. of Technology, Cambridge, Massachusetts 02139

Isotopic data for the Mesozoic tholeiites of Gondwanaland are used to evaluate theories explaining the chemistry of mantle-derived rocks; a crustal contamination hypothesis is discarded. These findings may contribute towards an understanding of crust-mantle evolution.

BECAUSE of the potential importance of Rb-Sr mantle isochrons^{1,2} in models of igneous petrogenesis, we have examined the published isotopic data for the Mesozoic tholeiites of Gondwanaland. These tholeiites were chosen because they are the product of roughly synchronous magmatism distributed over a vast surface area and they share a similar mode of occurrence and major element chemistry. Thus they can be used to appraise the question of primary versus contaminated chemistry in mantle-derived rocks and also the possibility that plateau-type tholeiites contain information on the local and regional heterogeneities in Earth's mantle.

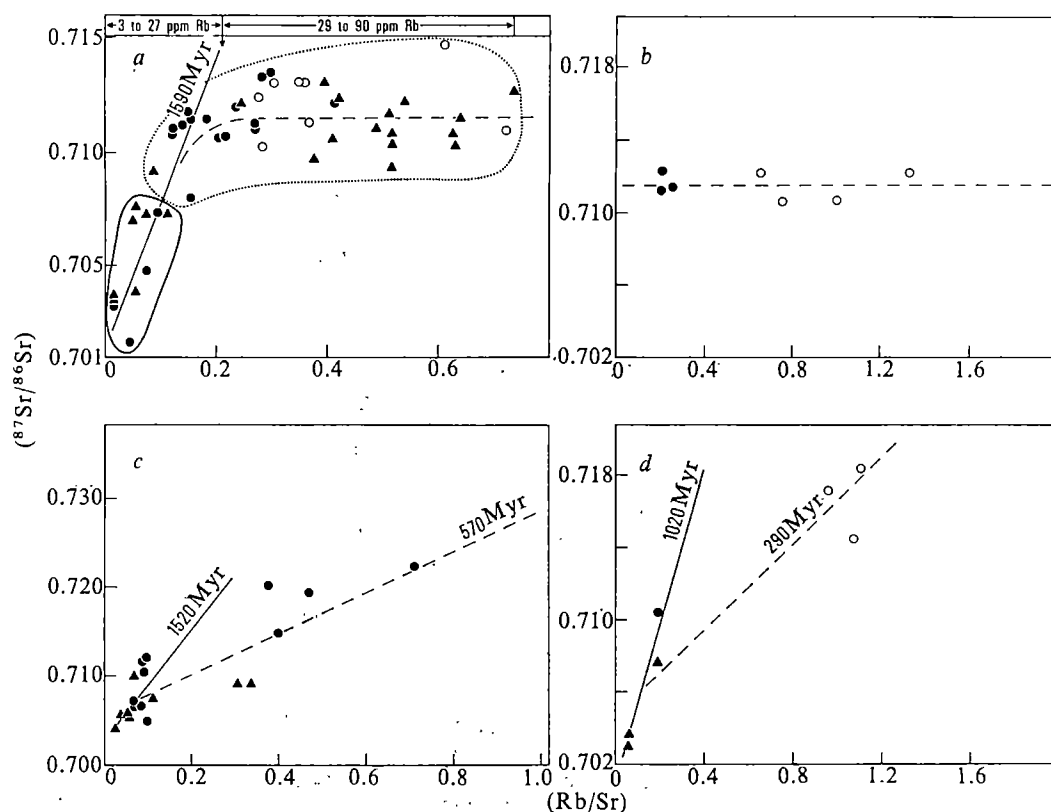

Mantle isochron properties

All available Rb/Sr and Sr-isotopic data for these tholeiites have been retrieved from the literature, grouped according to geographic distribution both within and between the individual post-Gondwanaland continental fragments, and examined for Rb-Sr mantle isochron properties. We have corrected the retrieved ⁸⁷Sr/⁸⁶Sr ratios for their post-crystallisation component by applying a blanket 160 Myr age correction. The Rb/Sr of the samples is such that real variation in this correction age has little influence on the calculated initial ⁸⁷Sr/⁸⁶Sr values. The resulting initial ⁸⁷Sr/⁸⁶Sr versus Rb/Sr data for each association are presented in Fig. 1. Each plot includes the more felsic members of each association (for example, the pegmatoids of the Ferrar Group; the Rio Grande do Sol felsics of the Serra Geral Formation; the Red Hill granophyres of Tasmania). Inspection of the diagrams reveals that good correlations occur for three of the five associations (Karoo, Serra Geral

and Queen Maud Land dolerites) while the remaining two associations (Ferrar Group and Tasmanian dolerites) define horizontal lines corresponding to a small range in initial ⁸⁷Sr/⁸⁶Sr for a wide range in Rb/Sr. Furthermore, for two of those associations showing correlations, rejection of the felsic members with high Rb/Sr leads to a correlation which, if interpreted as an isochron, corresponds to a much older age (Fig. 1c, d). The relevant statistical data for these correlations together with literature sources and number of samples are given in Table 1; the resulting best-fit lines are significantly different from zero at levels of confidence usually greater than 95%.

There are a variety of mechanisms which could produce correlations of the type observed in Fig. 1 and no obvious criteria to permit distinction between a crustal and mantle-related process. There is, however, considerable evidence against crustal contamination as the cause of these correlations. For the Mesozoic tholeiites such evidence would include lack of 'mixing line' relationships between all of the elements analysed, despite the thesis that the variability in isotopic composition is due to variable assimilation of that contaminant. This is well illustrated for the Kirkpatrick Basalts of Antarctica³, the proposed effusive phase of the Ferrar dolerites⁴. These basalts show initial Sr versus major element correlations for SiO₂ and total Fe, and a single contaminant is advanced to explain this correlation. However, the Sr-isotopic composition does not correlate with many of the other major elements (including Na and K) nor with Rb. The latter is higher in concentration than levels normally observed in basaltic magmas and any mixing-contamination explanations must satisfy the Rb observations. Other evidence would be an unlikely composition of supposed contaminant; any reasonable contamination mechanism will probably involve more than one rock composition; however, the average contaminant must correspond to some reasonable rock not too different in composition from that of the average crust. For the Kirkpatrick basalts, the proposed contaminant had a CIPW norm composition of:

Fig. 1 Rb/Sr versus initial $^{87}\text{Sr}/^{86}\text{Sr}$ for Mesozoic tholeiites. ●, Dolerites; ▲, basalts; ○, felsic members (such as dacites, granophyres); solid line mantle isochrons are for the less differentiated samples ($\text{Rb}/\text{Sr} < 0.2$, that is, $\text{SiO}_2 < 53\%$) and the dashed-line mantle isochrons are for all the data from each association (including felsic members if available). For literature sources see Table 1. *a*, Antarctica: Ferrar Group (including Kirkpatrick basalts) enclosed in dotted-line field; Queen Maud Land dolerites enclosed in solid-line field. The range of Rb values (p.p.m.) is included for reference. The solid-line mantle isochron is for the Queen Maud Land samples only. *b*, Australia: Tasmanian dolerites and granophyres. *c*, South Africa: Karroo dolerites and basalts (including samples from the Lebombo Nuanetsi Igneous Province). *d*, South America: Serra Geral Formation.

ferrosilite, 28%; quartz, 25%; albite, 19%; orthoclase, 18%; Na-metasilicate, 4%; diopside, 3%; ilmenite, 1%; apatite, 1%. While it is possible that mixtures of some crustal assemblages could produce a contaminant of this composition, it is highly unlikely that such a contaminant could exist in sufficient quantities to account for the wholesale contamination required by the model. Similar conclusions were reached by Weigand and Ragland⁵ in discussing the origin of the Mesozoic tholeiites of eastern North America.

The many other similar arguments would not strengthen our case against crustal contamination, but rather dilute it in prolixity. We thus use the isotopic data for the Mesozoic tholeiites to render the crustal contamination hypothesis untenable.

Isochrons for oceanic tholeiites

In oceanic regions, remote from contamination by continental crust, correlations of the type shown in Fig. 1 often occur².

Table 1 Rb-Sr mantle isochron data for Mesozoic tholeiite associations of Gondwanaland

Location	Association	MIRA	MIIR	<i>r</i>	<i>N</i>	Reference

THOLEIITES						
	Gondwanaland average data plus oceanic tholeiites, excluding Serra Geral value	1,620 ± 55	0.7023 ± 1	0.98(4)	14	2, and above list

All ± values given at 1σ. Details of mantle isochron regression procedures given in ref. 1. MIRA, mantle isochron regression age (Myr); MIIR, mantle isochron initial ratio; *r*, Pearson correlation coefficient (the numbers in parenthesis are increments of the standard deviation and indicate the level of confidence at which the slope of the fitted regression line differs from zero); *N*, samples included in the regression (the numbers in parenthesis are the numbers of available samples excluded); *b*, basalt; *d*, dolerite; *d¹*, dacite or rhyodacite; *g*, granophyre; *p*, pegmatoid; n.s., not significant. All averaged data from Table 2.

Fig. 2 Rb-Sr mantle isochron (solid line) for oceanic and Mesozoic tholeiites. Each point represents an average of available data on individual samples from either a given island, island group (●) or continental association (○). Numbers refer to the data index in Table 2.

For average island tholeiites these correlations correspond to an age of $1,600 \pm 200$ Myr, which is remarkably concordant with the Pb-Pb isochron ages of oceanic basalts ($1,800 \pm 100$ Myr). Because of this concordance between radiometric systems in which the systematics differ markedly during petrogenesis (especially during variable degrees of partial melting and differentiation), we argued that the Rb/Sr data defined a mantle isochron dating a real event, possibly the separation of an isolated asthenosphere (and mesosphere) within a previously more uniform and convecting mantle. In arriving at the 1,600 Myr Rb-Sr mantle isochron for oceanic tholeiites, we averaged the data from each island or island group, excluding any differentiate samples which could have influenced the systematics. The same treatment has been applied to the Mesozoic tholeiites, where differentiation has played a significant part in their magmatic histories as revealed by major element compositions (for example, refs 6, 7). Because only a few isotopic analyses have accompanying major and trace element data we could not independently identify the more primitive samples. Examination of available major element, trace element and petrographic data, however, indicate that the Rb/Sr ratio is extremely sensitive to bulk chemistry and can be used in place of a major or trace element index of differentiation. It was found that a Rb/Sr ratio of about 0.2 corresponds to an SiO_2 level of approximately 53%, and hence samples with an Rb/Sr ratio of 0.2 or less have chemical compositions more like 'normal' basaltic tholeiite. It is recognised that samples with Rb/Sr less than this value could also be somewhat differentiated and we emphasise that the Rb/Sr cut-off of 0.2 is used merely to distinguish between the more and less differentiated tholeiites. The effects of this differentiation on the mantle isochron systematics is well illustrated by the Karroo and Serra Geral tholeiites. Rejection of samples with Rb/Sr > 0.2 leads to significantly older mantle isochrons in the range of 1,000 to 1,500 Myr (Fig. 1 and Table 1). Clearly, differentiation rotates the mantle isochrons to younger ages, thereby masking source-region age information.

The calculated average values for initial $^{87}\text{Sr}/^{86}\text{Sr}$ and Rb/Sr of the least differentiated samples from each association are listed with the modern oceanic tholeiite data in Table 2 and plotted in Fig. 2. The Mesozoic data plot along the extension of the oceanic tholeiite mantle isochron with the exception of the Serra Geral Formation, where weathering may have rendered the data suspect. Published data for the Tasmanian samples all have Rb/Sr > 0.2, and so were excluded from this plot, but unpublished data with Rb/Sr < 0.2 have been included in Fig. 2 (these data will be the subject of a separate paper). When treated together, the tholeiite data define a 1,620 Myr mantle isochron (Table 1) with a 1σ error

Table 2 Average Rb/Sr and initial $^{87}\text{Sr}/^{86}\text{Sr}$ for tholeiites from oceanic islands[†], ocean floors[†] and the Gondwanaland Mesozoic tholeiite associations (this paper)

Average data for least differentiated tholeiites (Rb/Sr < 0.2).

(± 55 Myr) comparable to that of geochronological-type isochrons used for standard stratigraphic purposes. This alignment of oceanic island and Mesozoic tholeiite data along a common isochron would seem to require an exceptional coincidence if crustal contamination is the reason for the high $^{87}\text{Sr}/^{86}\text{Sr}$ ratios in the Mesozoic tholeiites. We consider this to be significant evidence against crustal contamination as a cause for the elevated and variable Sr isotope ratios in these tholeiites. It is also contradicts previous arguments for the bulk assimilation of crustal material in their petrogenesis, and encourages the interpretation of the isotope compositions of these rocks in terms of primary mantle properties.

Gondwanaland regional variations

When the five associations studied in this paper are plotted on a reconstructed Gondwanaland⁸, they define two geographic

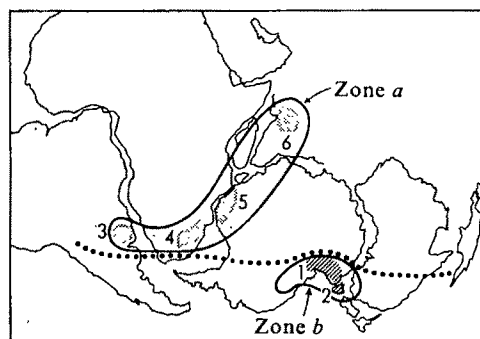

Fig. 3 Location of Mesozoic tholeiite associations plotted on Smith and Hallam's⁸ reconstruction of Gondwanaland. The continental interior margin of Du Toit's²⁴ Samfrau geosyncline is shown (heavily dotted line). Zone *a* includes Mesozoic tholeiites that have traversed stable cratonic interiors of the continents while Zone *b* includes those tholeiites that have traversed cratonic-margin regions. 1, Ferrar Group including the Kirkpatrick basalts; 2, Tasmanian dolerites of south-east Australia; 3, Serra Geral Formation, South America; 4, Karroo dolerites including the Lebombo-Naunetsi Igneous Province, South Africa; 5, Queen Maud Land dolerites of Antarctica; 6, Deccan Traps, India.

provinces (labelled zones *a* and *b*, Fig 3). These two provinces differ in several ways. Zone *a* tholeiites have traversed ancient basement rocks (2,000 Myr or older; refs. 9–13) constituting the cratons of each post-Gondwanaland fragment, while zone *b* tholeiites have been emplaced in a cratonic margin region dominated by late Precambrian and Palaeozoic orogenesis (basement ages in the range 400 to 1,000 Myr; refs. 14–17). Zone *a* has 'normal' surface heat flux values typical of cratonic regions while zone *b* is characterised by heat flow values about twice those of zone *a*^{18, 19}. Zone *a* tholeiites show mantle isochrons, zone *b* tholeiites do not. Zone *a* tholeiites show lower average ⁸⁷Sr/⁸⁶Sr ratios (0.7064) than zone *b* tholeiites (0.7112).

Considering these differences, we suggest that the lithosphere under zone *b* is significantly more enriched in radioactive heat producing elements than that underlying zone *a*. A relative enrichment in zone *b* lithosphere of K, Rb and U would lead to higher surface heat flow values and higher ⁸⁷Sr/⁸⁶Sr ratios. The lack of mantle isochrons in zone *b* tholeiites may reflect a relatively homogeneous or well-mixed lithosphere in this region. This suggests that zone *b* lithosphere may be composed dominantly of 'enriched' mesosphere-derived material relative to more depleted asthenosphere components. Also, high initial ⁸⁷Sr/⁸⁶Sr ratios (0.71 or more) are pervasive in many mafic igneous rocks that have been emplaced in the Australian sector of the Samfrau Geosyncline^{17, 20} (L. Black, personal communication, C. B., unpublished data) indicating a consistent regional anomaly in the source region corresponding to zone *b*. In Fig. 3, we have extended zone *a* to India because the Mesozoic tholeiites of that sub-continent (Deccan Traps) occur within a craton with basement of at least 2,500 Myr²¹. It could be predicted that, when data become available, the Deccan Traps will also show Rb–Sr mantle isochrons, although whether the accompanying range in initial ⁸⁷Sr/⁸⁶Sr resembles that of the Karroo and Serra Geral tholeiites or that of the Queen Maud Land dolerites awaits investigation. Based on our analysis of the Mesozoic tholeiites of Gondwanaland, a case can be made for the existence of gross heterogeneities in the underlying lithosphere manifest on all scales from local to continental, and for the development of those heterogeneities during an event perhaps associated with the separation of asthenosphere from mesosphere 1,600 to 1,700 Myr ago. Furthermore, we find that the cratonic margin part of Gond-

waland's lithosphere is probably much more enriched on average than the regional sub-cratonic lithosphere. It is not accidental that this enriched lithosphere correlates with areas of high heat flow, numerous anatectic granites^{22, 23}, high incidence of economic mineralisation of diverse types, and anomalous Sr-isotope composition in many mafic igneous rocks of Precambrian to Palaeozoic age. Indeed one may speculate that the reactivation of that sector of Gondwanaland during the late Precambrian and Palaeozoic was due primarily to the enriched nature of the underlying lithosphere. Clearly we have left many questions unresolved and there are many new ones provoked, but we are confident that investigations orientated to searching for and understanding Rb–Sr mantle isochrons will have a profound effect on our understanding of crust–mantle evolution.

Structure of vancomycin and its complex with acetyl-D-alanyl-D-alanine

George M. Sheldrick, Peter G. Jones, Olga Kennard, Dudley H. Williams & Gerald A. Smith*

University Chemical Laboratory, Lensfield Road, Cambridge, UK

Vancomycin, a broad-spectrum antibiotic, inhibits the growth of cell walls by complex formation with peptides terminating in D-alanyl-D-alanine. The structure of vancomycin was determined by X-ray analysis of the degradation product CDP-I. A model of the complex is proposed based on this study and spectroscopic data.

THE antibiotic, vancomycin, was first isolated in 1956 from cultures of *Streptomyces orientalis*¹. Although much studied; its full chemical structure could not be established. It is a broad-spectrum antibiotic but because of adverse side effects, its use is restricted to the treatment of staphylococcal infections (for example, septicaemia, pneumonia and wound infections) when

other antibiotics are ineffective. There are no naturally occurring strains of bacteria known to be resistant to vancomycin, nor do bacteria readily develop resistance to it. Clinical studies of vancomycin have been reviewed by Lightbown².

Vancomycin is known to act by inhibiting the biosynthesis of the cell-wall mucopeptide, leading to a cessation of growth and the eventual destruction of the cell by lysis. Perkins has shown^{3–5} that it forms complexes with the nucleotide-*N*-acetyl muramyl pentapeptide precursor, the reaction being specific for peptides with D-alanyl-D-alanine at the carboxyl terminus. Such complex formation either with the lipid intermediate or with uncross-linked peptidoglycan would inhibit mucopeptide biosynthesis and thus account for the antibiotic action. A more detailed understanding of this complex formation, however, is not possible without a knowledge of the molecular structure of the antibiotic.

*Present address: Department of Biochemistry, Tennis Court Road, Cambridge, UK.

Fig. 1 The structure of CDP-I.

The structure of vancomycin has now been determined from an X-ray analysis of CDP-I⁶, a degradation product obtained from vancomycin with loss of ammonia. The solution of the structure, which contains 101 atoms (excluding hydrogens) in the asymmetric unit as well as 33 disordered water molecules, was obtained by direct methods, with the minimum use of chemical information. The analysis was based on full data out to a resolution of 0.8 Å, and without such extensive data it is unlikely that the structure could have been solved by the techniques available at present.

X-ray analysis of CDP-I confirms the structural units deduced from chemical, nuclear magnetic resonance (NMR), and mass spectrometry experiments⁶⁻¹². The principal units in the structure, summarised in Fig. 1, are a disaccharide linked to three aromatic rings; *N*-methylleucine; aspartic acid and a biphenyl system. These units are linked by secondary amide bonds, to form a tricyclic molecule, containing *N*-terminal *N*-methylleucine and two free carboxyl groups.

Aspects of the conformation of vancomycin in DMSO solution (from NMR data) correlate closely with the three-dimensional structure determined by X rays. There are thus no substantial conformational changes resulting from hydration or crystal forces. We present here details of the X-ray analysis, the three-dimensional structure and some suggestions concerning the mode of binding of acetyl D-alanyl-D-alanine to vancomycin. If suitable crystals can be obtained, we hope to test these speculations by an X-ray analysis of such a complex.

Experimental details

Large crystals of CDP-I were obtained by dissolving vancomycin in water, adjusting the pH to 4.2 with a few drops of 0.05 N aqueous NaOH, and keeping the resulting solution at 70–80 °C for 40 h. During the course of the reaction, large, highly insoluble amber crystals separated out, one of which was cut to a rectangular block 0.7 × 0.3 × 0.2 mm and mounted in a capillary tube in contact with some mother liquor. Cell constants were measured on a 4-circle Syntex diffractometer using Cu Kα radiation (Table 1). The cell dimensions were slightly larger than previously reported¹³, probably because of increased hydration in this sample.

In total, 11,986 reflections, including Friedel pairs, were measured on the diffractometer in the range $0 < 2\theta < 101^\circ$ giving 7,759 unique reflections with $F > 3\sigma(F)$. A repeatedly monitored reference reflection decreased in intensity by ~20% during the 5 weeks of data collection and other intensities were scaled accordingly.

Solution of the structure

Numerous fruitless attempts were made to solve the structure using both Patterson and direct methods. Eventually a chemically sensible fragment, containing a six-membered ring and an atom

assumed to be chlorine, emerged fortuitously from one of the E-maps. Tangent expansion and guesswork extended this to the three aromatic rings of the central nucleus and the two chlorine atoms. All attempts to expand this fragment, including the use of translation functions, were unsuccessful, until the geometry had been optimised by least-squares refinement with distance constraints. A single tangent expansion then produced 80 atoms, all of which could be identified with the units deduced chemically. Further atoms, including the water molecules, were located from difference syntheses.

The structure has now been refined to a current R of 16%. All atoms except Cl are isotropic. Fifty-four H atoms were included at calculated positions (C–H 1.08 Å, H–C–H 109.5°); 33 water molecules were located, with site occupancy factors varying from 0.47 to 1. The temperature factor for the disordered water molecules was fixed at 0.15 Å². Refinement is continuing. The absolute configuration has not been determined from the X-ray data, but it must be that shown in Fig. 2 from the known stereochemistry of chemically isolated fragments.

The structure

As already mentioned, all the units deduced from chemical and spectroscopic evidence have been confirmed by the X-ray structure. These include the amino sugar vancomamine, two β -hydroxychlorotyrosine units and three oxygenated phenylglycine systems as well as *N*-methylleucine and aspartic acid. It is unusual that in the latter, the α carbonyl is present as the free carboxyl group. The structure also contains a relatively rare *cis* amide bond.

The molecule is extremely compact, as can be seen from the space filling drawing of Fig. 3. It carries a marked cleft on the side of the molecule bearing the Cl atoms, but also a less well-defined cleft on the other side. There is no space for any water molecules inside the tricyclic ring system.

The molecules are linked in the extended crystal structure by a complex system of hydrogen bonds. There are only five hydrogen

Fig. 2 ORTEP¹⁶ plot of CDP-I. The *cis* amide bond is arrowed; H atoms are omitted. Anisotropic atoms are chlorine.

Fig. 3 Space-filling plot of CDP-I (same orientation as Fig. 2, using the program PLUTO, W. D. S. Motherwell, unpublished). The following radii were used (Å): C, N, O all 1.4; Cl 1.7; H 0.9. Only H atoms attached to C are included.

bonds which do not involve water: the carboxyl of aspartic acid to OH of the trisubstituted ring of the biphenyl, NH_2 of methyl-leucine to carboxylate of the biphenyl, O4 of the glucose to NH of the diaryloxyphenyl-glycine and O4 of vancosamine to the carboxylate and NH of aspartic acid. The remaining hydrogen bonds are between the CDP-I molecule and water molecules, and between the water molecules themselves, forming an intricate three-dimensional network.

CDP-I is obtained from vancomycin by the loss of ammonia. The free carboxyl group on the biphenyl group of CDP-I is known also to occur in vancomycin. The structure of vancomycin is therefore that shown in Figs 1 and 2 except that the carboxyl group of the aspartic acid is changed to a primary amide ($-\text{CONH}_2$).

Mode of binding

The molecular basis of the antibiotic action is probably associated with the binding of acyl-D-Ala-D-Ala fragments into the cleft of the molecule on the face bearing the chlorine atoms. Earlier NMR studies^{14,15} have shown that the C-terminal alanine methyl resonance of Ac-D-Ala-D-Ala is heavily shielded in the presence of vancomycin. Later work¹² established that binding of Ac-D-Ala-D-Ala to vancomycin caused marked downfield shifts of protons

Fig. 4 Schematic illustration of a possible interaction between Ac-D-Ala-D-Ala and a portion of the vancomycin molecule.

H_b and H_c , and a marked upfield shift of H_a (Fig. 1). It is likely that these protons are near to the peptide fragment in the antibiotic-peptide complex, and in particular that NH_c is hydrogen bonded to a peptide carbonyl group. On the basis of this evidence, and an examination of space-filling models, we propose that vancomycin associates with the backbone of Ac-D-Ala-D-Ala as shown in Fig. 4, where the aromatic residue (Ar) is the trioxxygenated benzene ring bearing the disaccharide. In the proposed complex, the C-terminal methyl group of Ac-D-Ala-D-Ala lies above the face of this benzene ring, thus accounting for its upfield shift on complex formation. The other secondary methyl group of Ac-D-Ala-D-Ala lies near the benzene ring which carries two phenolic hydroxyl groups, but is not located centrally over it and so is not similarly shielded on complex formation.

This model, although consistent with the X-ray structure and spectroscopic results, is not necessarily a unique one, and further experimental evidence is needed to establish the precise mode of binding of the antibiotic-peptide complex.

We thank the MRC for financial support and the SRC for the provision of the diffractometer.

letters to nature

Positions of galactic

X-ray sources: $320^\circ < l^{\text{II}} < 340^\circ$

PRECISE ($20-40''$) positions of seven X-ray sources in the celestial region $320^\circ < l^{\text{II}} < 340^\circ$ are reported here. These include a recurrent transient X-ray source (MX1608-52; refs 1-4) and a source 2S1553-542 (ref. 5) coincident with a γ -ray source⁶ within the given errors of position. The positions reported here reduce the previously reported areas

of the error region for six of the sources by factors ranging between 10 and 100. In the case of MX1608-52, a preliminary report of this work⁷ led to the identification of an optical candidate^{7,8}. The present results add confidence to the proposed radio candidates for 4U1624-49 (ref. 9) and 4U1642-45 (refs 9, 10). But they eliminate proposed possible optical candidates^{5,11-14} for the sources 4U1543-62, 2S1553-542, 4U1624-49 and 4U1642-45.

The positions for the sources 4U1538-52, 4U1543-62, 2S1553-542, (MX1553-54), 4U1556-60, MX1608-52,

†1.0 μ Jy corresponds to 2.2×10^{-11} erg s^{–1} cm^{–2} (2–11 keV). $I_{\text{crab}} = 1,060$ μ Jy (see refs 15, 16).

‡At the time of observation (24 July, 1977).

4U1624–49, and GX340+0 (4U1642–45) are reported in Table 1 along with the estimated error radii¹⁵. The observations of six of these sources were carried out with the SAS-3 rotation modulation collimator from 16 June to 21 June 1975 as part of a survey of galactic source positions^{15–19}. The source MX1608–52 was observed on 24 July 1977 when it was in a bright state². In Fig. 1, we compare our results with other measurements and positions of radio and optical candidates for three of the sources. Finding charts for six sources are given in Fig. 2. Astrometry and photometry results for a few stars in the error regions are given in Table 2.

Ten other known X-ray sources lie in this region. SAS-3 positions for three of these (Cir X–1, TrA X–1 = A1524–61, MXB1636–53) were reported earlier^{17, 18}. The remaining seven were not seen in our survey. Of these, the sources 4U1543–47 and 4U1630–47 are known transients^{20, 21} and the source 4U1658–48 is known to be highly variable²². We place an upper limit of 10 μ Jy (2–11 keV) for these and the other four sources (4U1510–59, 4U1530–44, A1540–53 and 4U1631–64). The intensity of MX1608–52

was ≤ 5 μ Jy during the 1975 observations. These limits are consistent with the intensities and variability factors previously reported for these sources^{20, 22}.

We discuss briefly below the proposed radio and optical candidates for the sources:

4U1538–52: Cowley *et al.*²⁴ have measured the colours for ~ 50 stars in the Uhuru error region and have suggested several probable candidates for this source; stars numbered 10 and 12 in Fig. 2 are among these. This source is now known to be the same as A1540–53 (ref. 23), on the basis of new Ariel V position determinations²⁵ and is also known to be a pulsing binary system^{23, 25, 26}.

4U1543–62: The star suggested as a possible candidate by Penston *et al.*¹¹ (denoted as A in their Plate II) is excluded as a candidate.

2S1553–542: The variable star TT Normae and the B0 supergiant SAO243166 are near our error circle (Fig. 1). We previously suggested⁵ the latter as a candidate. Subsequently, failure to detect emission lines or velocity variations in its spectrum²⁷ weakened the proposed identification. This star is $\sim 1.2'$ away from the refined position given here and

Fig. 1 X-ray source positions and candidates for three sources. The SAS-3 error circles for the other sources are smaller in area than previous work by factors of 10–100. The positions are from Uhuru (U, ref. 20), and Ariel V (A, ref. 33) satellites, a rocket experiment³⁴, and the present work (S). The stars TT Normae and SAO243166 near 2S1553–542 and the star SAO226781 near 2S1624–490 are also shown. The position of the radio candidate⁹ for 4U1624–49 and the extent of a finite-sized radio source^{9, 10} coincident with 4U1642–45 are indicated.

Figure 1

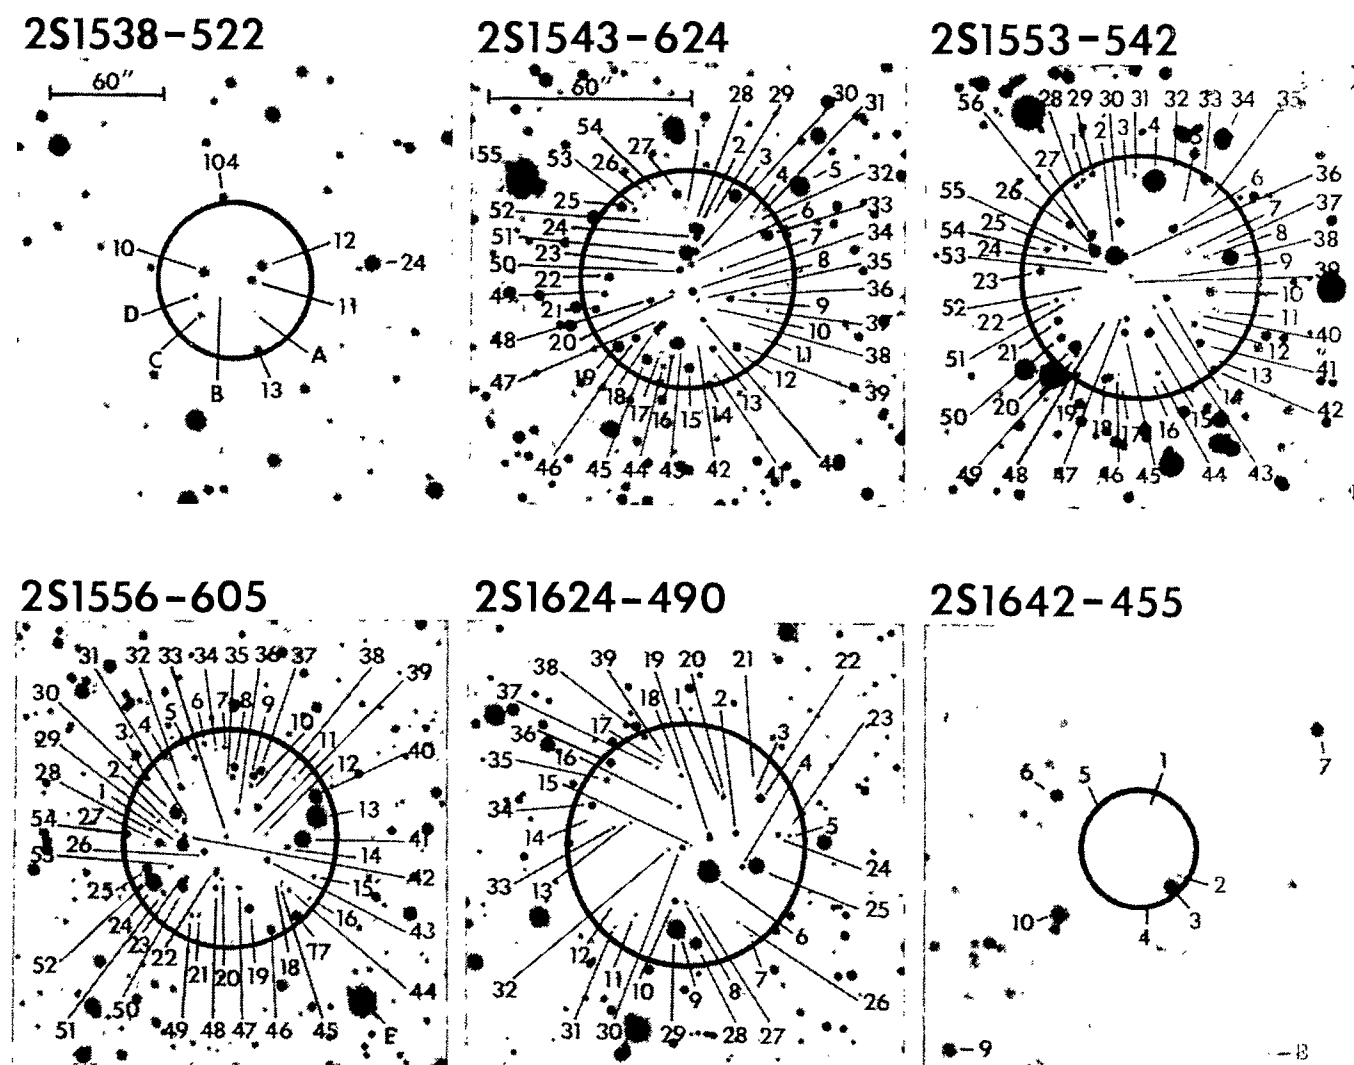

Fig. 2 Finding charts for six SAS-3 positions. A finding chart for 2S1608-523 is given by Grindley and Liller⁸. The charts for 2S1553-542 and 2S1624-490 are from R plates and those for 2S1543-624 and 2S1556-605 from B plates taken with the CTIO telescope by W. A. Hiltner and C. Canizares; see chart 2S1543-624 for scale. The other two charts are from the ESO quick-blue survey; see 2S1538-522 for scale. We adopted the numbering scheme of ref. 24 for 2S1538-522 and the lettering scheme of ref. 11 for 2S1556-605. North is up and east is to the left.

is excluded as a possible candidate. This source is within the 1° radius error circle of the γ -ray source CG327-0 discovered by the COS-B satellite⁶.

4U1556-60: The star¹⁴ SAO253382 excluded as a candidate by the Copernicus satellite measurement^{11,28}, is also excluded by the present observation.

MX1608-52: The star SAO243445 within the Uhuru error box²⁹ (denoted as star A in Fig. 1 of ref. 29) is excluded by the present measurement. Grindley^{7,8} reports a candidate star within our error circle, which brightened from $V > 23$ mag in August 1976 to $V = 21 \pm 1$ mag in August 1977. The present position is within the error region of the Norma X-ray burst source^{30,31}.

4U1624-49: The radio source G334.9-0.3 proposed by Sanduleak and Dolan⁹ as a candidate is supported by the present measurement (Fig. 1). The star SAO226781 considered as a possible candidate¹¹⁻¹⁴ is excluded by the present observation.

4U1642-45: The extended radio source G339.6-0.1 proposed by Sanduleak and Dolan⁹ and by Seaquist¹⁰ as a candidate is supported by the present observation (Fig. 1). Seaquist¹⁰, on the basis of the flat radio spectrum, suggests that the radio source is an HII region. The star suggested as a possible candidate by Penston *et al.*¹¹ (denoted as A in their plate III) is excluded by the present measurement.

We thank the staffs of the Center for Space Research at MIT and the Goddard Space Flight Center of NASA for their support. We thank C. Canizares, R. Kelly, J. Kulik, J. McClintock, E. Ng, and C. Reid for helpful conversations. This work was supported in part by the US National

Dynamic measurement of matter creation

If a rotor could be spun so that it had an inertial decay time $\sim 10^{11}$ yr, 10^{18} s, it could test matter creation cosmologies¹⁻³ at a significant level. The advantage of this method over previous ones⁴⁻⁸ is that the result is independent of the form in which matter is created, providing it stays in place. We have designed an experiment to test this process; it is under construction and is described here. It consists of an inertially spinning rotor suspended inside another rotor, a modification of the double magnetic suspension⁸. Past measurements or estimates have not unequivocally answered the question of matter creation. Cohen and King⁴ established an upper limit of 4×10^{-23} g per g per s on the creation rate of hydrogen in mercury metal. Gittus⁵ suggested that matter created in rocks takes the form of interstitial atoms which diffuse into dislocations. Towe⁶ disputed this, noting that if mass proportional creation were occurring, 30% of the atoms in old terrestrial rocks would occupy interstitial positions and this would result in lattice disruptions. Gittus⁷ later proposed that the matter multiplication rate for crystalline materials could be found by determining the ratio of the shear modulus to the crystal viscosity. He suggested that a reasonable estimate for the sensitivity of the method might be 3×10^{-18} atoms per atom per s, although this has not been tested. In a geophysical argument, Wesson⁸ can account for

the observed expansion rate of the earth by appealing to a mass proportional matter creation whose rate is 7×10^{-18} g per g per s, but he notes that this is in conflict with the result of Cohen and King; it exceeds Dirac's prediction by several times.

Figure 1 shows the elements of the experiment. Two cylinders of highly temperature-stable ceramic rotate concentrically about the axis of rotation of a precision turntable. The outer cylinder is connected to the turntable which rotates with an integral speed constancy limited only by the precision of the atomic clock. The turntable drive is a 50-pole magnetic-averaging synchronous direct drive and the sensor is a double-plate totally averaging encoder system.

The inner (inertial) cylinder is magnetically suspended from the outer and initially caused to rotate with the outer, after which it is freely rotating. Mass created in the inner cylinder causes it to slow down relative to the outer cylinder. The accumulated phase lag of the inertial cylinder provides an extremely sensitive measure of this relative motion. A synchronised pulsed laser has a split beam, part of which is for sensing the relative angle of the two cylinders and another part of which, when unblocked, provides forward or backward momentum impulses to the inertial cylinder to keep it in phase. The sequences of the pulses constitutes the signal. Before and after experiments calibrate the momentum impulses and also provide estimates of limits on competing energy loss mechanisms when the inertial cylinder is driven up to speed from rest with the turntable stationary.

Three major competing mechanisms for energy loss among many^{9,10} are (1) viscous losses in the residual gas of the vacuum, (2) magnetic hysteresis in the support, and (3) interaction with external magnetic fields. Another consideration is the change in cylinder radius due to thermal expansion, and a further major factor is the wandering of the inertial cylinder about its equilibrium position due to thermal noise.

The viscous losses and magnetic hysteresis are rendered virtually zero by the feedback system described above which allows essentially no relative motion between the cylinders. Shields can reduce asymmetric (hysteresis) effects of external magnetic fields to insignificant levels. Thermal expansion effects are kept negligible if the system is thermally isolated and allowed to come to temperature equilibrium, $\Delta T \leq 10^{-3}$ K and by making the cylinder of a material with temperature coefficient $\alpha < 10^{-7}$ K⁻¹. In this case $\Delta r/r < 10^{-10}$ and constitutes a short term variation only, not a steady drift.

The thermal fluctuations can be estimated from standard noise criteria:¹¹

$$\frac{1}{2} I (\Delta \omega_n)^2 = -\frac{1}{2} kT, \quad (1)$$

where I is the inner cylinder moment of inertia, kT is the thermal energy and $\Delta \omega_n$ is the thermally caused fluctuation in velocity.

Then if

$$\Delta \theta_n = \int \Delta \omega_n dt, \quad (2)$$

is the angle through which the cylinder has random-walked from synchronous position due to noise, we get

$$\Delta \theta_n = (kT/I)^{1/2} \tau, \quad (3)$$

where τ is the duration of the experiment.

The magnitude of the expected change in angle due to mass creation depends on the particular cosmology by which it is predicted. If the newly created matter has the same velocity as the matter in the inertial cylinder, then no effect might be measured even if mass creation existed. But as the newly created matter presumably owes its existence in some way to the Universe as a whole, we might expect its initial state to reflect the overall rotation of the Universe which we presume to be zero. In this case, there would be some 'drag' on the inner cylinder.

There are still many possibilities, three of which we will mention. First, angular momentum, L , is conserved and mass

Fig. 1 Two cylinders of temperature-stable ceramic (Zerodur) rotate concentrically in an evacuated region inside an acoustic and magnetic shield. The inner cylinder is magnetically suspended from the outer one which rotates with precise angular velocity ω . Mass created in the inner cylinder tends to slow it down. A feedback system employing laser pulse sensing and photon driving keeps the inner cylinder velocity ω' very near to ω . Forward-backward asymmetry needed in these feedback driving pulses to keep $\omega' = \omega$ constitutes the signal. With the two cylinders running synchronously, viscous, magnetic hysteresis and other damping effects are kept near zero.

is created with no angular momentum and in such a way that the dimensions of the cylinder remain constant. If I = moment of inertia, M = mass, and r = radius of the cylinder, then L = constant = $I\omega \sim Mr^2\omega$ which gives $\dot{\omega}/\omega = -\dot{M}/M$. Second, L conserved; mass created with no angular momentum and density is conserved. As the arguments are dimensional, we will treat the height of the cylinder as the radius, then L = constant = $\rho^{-2/3} M^{5/3} \omega$ which gives $\dot{\omega}/\omega = -5/3 \dot{M}/M$.

Third, large numbers hypothesis as for instance in ref. 1. Under the LNH angular momentum is not conserved in atomic units. Velocity and atomic quantities are constant. If the new matter is created such that density, which is an 'atomic' property is constant, then $\omega \sim v/r \sim v(\rho/M)^{1/3}$, or $\dot{\omega}/\omega = -1/3 \dot{M}/M$. (It is possible to analyse a rotor in more than one way under the LNH; for example, the spinning earth is gravitationally bound and, hence, its density is not purely an atomic property. In this case the analysis might proceed more along the lines of an orbit problem and one gets $\dot{\omega}/\omega \sim -1/2 \dot{M}/M$).

In all of these cases we find $\dot{\omega}/\omega = Y\dot{M}/M$ where Y is a number of order unity. Typical estimates for \dot{M}/M are $2 \times 10^{-10} \text{ yr}^{-1} = 6 \times 10^{-18} \text{ s}^{-1}$. If the inner cylinder has no initial motion relative to the outer, then after a time τ we would have an angular displacement

$$\delta\theta = \omega\tau^2 = -Y\omega\dot{M}/M \tau^2. \quad (4)$$

Thus, the lag angle increases quadratically in time. Equations (3) and (4) can be combined to give the signal-to-noise ratio $\delta\theta/\Delta\theta_n$, from which the sensitivity to mass creation is

$$\dot{M}/M = [(\delta\theta/\Delta\theta_n) (kT/I)^{1/2}] / Y\omega\tau \quad (5)$$

Without feedback, the sensitivity from equation (5) at room temperature, with $I = 25,000 \text{ g cm}^2$ and $\omega = 10 \text{ rad s}^{-1}$ would be $\dot{M}/M = 10^{-8}$. Feedback if noiseless and of gain G can reduce the effective temperature¹¹ by a factor of $\sim (G)^{1/2}$, and the experiment ultimately will be cooled as well. Appropriate feedback will be controlled by a digital processor. Thus the signal-to-noise condition can be met simultaneously with the

low damping requirement. To emphasise the level of difficulty of the experiment we note, from the secular decrease in the earth's rotational angular velocity¹², largely due to tidal friction, that the earth itself as a rotor is too dissipative by a factor of 20. Braginsky¹³ has shown from noise considerations and fundamental limits on detection sensitivity that mechanical oscillators can in principle have decay times $\sim 10^{-18} \text{ s}$. Similar limits apply to rotors and estimates with our parameters are that this can even be improved.

Ultimately, an observed effect would always be suspected of unaccounted-for-damping, yet most damping effects are expected to be linear in time to a close approximation and the signal is quadratic so that it has a distinctive signature. Nevertheless, if an effect is observed the experiment will be repeated at different initial angles, with different cylinders, and at different temperatures.

Identification of interstellar polysaccharides and related hydrocarbons

INFRARED transmittance spectra of several polysaccharides which are suitably calibrated for comparison with astronomical data have been obtained. We show here that a mean 2.5-15 μm spectrum computed from our measurements is remarkably close to that required to explain a wide range of astronomical data, except for two significant points of departure. The required relative opacity at the 3 μm absorption dip is a factor ~ 1.5 lower than we found in our laboratory measurements: this difference may arise from the presence of water ($\sim 10\%$) associated with terrestrial polysaccharide samples. In the 9.5-12 μm waveband an additional source of opacity seems to be necessary. The close agreement between the spectrum of this excess opacity and the absorption spectrum of propene C_3H_6 points strongly to the identification of hydrocarbons of this type which may be associated with polysaccharide grains in interstellar space.

The presence of interstellar polysaccharides has been deduced¹ by comparing infrared spectra of several galactic infrared sources in the 2-30 μm waveband with model calculations based on transmittance data for cellulose. We show here that the transmittance properties of cotton cellulose gives a good agreement to the observed emission from the Trapezium nebula in the 8-30 μm waveband. But with the adoption of more stringent standards of comparison between observations and theory, we thought it appropriate to 'optimise' the transmittance values over the waveband 2.1-13 μm without departing from the original cotton cellulose data by more than a reasonable margin. In the absence of properly calibrated transmittance data for other polysaccharides we have provisionally assigned our optimal values to a 'notional' interstellar polysaccharide ensemble. It is, therefore, desirable to obtain

experimentally a mean transmittance curve for several related polysaccharides.

Four polysaccharides: α -cellulose (α -cellulose fibre ~99.5% pure), amylose (from potato), arabinogalactan (from Larch wood) and mannan (from bakers yeast) were included in the present study. Samples supplied by Sigma London Chemical Company Limited were dispersed in KBr disks at concentrations

Fig. 1 Transmittance spectra of several polysaccharides dispersed in KBr. *a*, α -cellulose; *b*, amylose; *c*, arabinogalactan; and *d*, mannan. Concentrations are about 1% with respect to KBr. Spectra shown here were obtained using a Perkin-Elmer 137 Infracord Spectrophotometer.

of about 2 mg per 200 mg KBr, and spectra obtained using either a Perkin-Elmer 137 Infracord spectrophotometer or a Perkin-Elmer 257 Infrared spectrophotometer. The spectrophotometer was adjusted to give a 100% transmittance reading at all wavelengths in the absence of the mounted disks. Thus the measured transmittance (%) corresponds to $100 \exp(-\tau_\lambda)$ where τ_λ is the opacity of the laboratory samples. All these spectra (Fig. 1) show the characteristic signatures of polysaccharides, with principal absorptions centred on 3, 3.4, 6 and 9.5 μm . The solid curve in Fig. 2 shows the mean transmittance curve $\exp(-\langle\tau\rangle)$ computed from the spectra in Fig. 1.

Fig. 2 Mean transmittance spectrum for four samples from Fig. 1. Dashed segments represent optimised variations to give best fit to astronomical spectra.

The agreement of this curve with the spectrum of α -cellulose is close, so our earlier attempts to use a smoothed-out cellulose transmittance curve to represent the properties of interstellar polysaccharides would seem to be justified.

We shall now use our mean polysaccharide transmittance curve to interpret spectra of galactic infrared sources. Using our cascade model for the formation of polysaccharides in mass flows from stars^{2,7} infrared spectra were computed from several sets of transmittance data. Although tolerable fits to astronomical spectra are obtainable with any one of the transmittance curves in Fig. 1 or with the mean curve (solid line) in Fig. 2, the requirement for an excellent fit to a wide range of observations demands minor modifications to our mean polysaccharide transmittance data. These modifications are indicated by the dashed lines in Fig. 2. Figure 3 shows the detailed agreement which is obtained using this modified transmittance data in a source calculation for the BN object. The excellent agreement between observations and theory gives strong empirical support for the modifications proposed here. But even these apparently minor departures from our polysaccharide mean data need interpretation.

The general similarity of the empirically estimated optimal transmittance data to the mean polysaccharide curve is very close except in two respects. (1) The value of $\tau(3\mu)$ for the experimental samples (and the mean curve) are a factor ~1.5 higher than what we infer from astronomical observations. We are most probably seeing here the effect of significant amounts of H_2O associated with freeze-dried terrestrial polysaccharides. Astronomical polysaccharides will be largely free of water, and the 3 μm absorption significantly shallower. A factor ~1.5 could well arise due to this effect. We note that a

Fig. 3 Solid curve is infrared emission for the source BN calculated for the model of Hoyle *et al.*⁷. The formation temperature of polysaccharides was taken as 850 K and the grain temperature was taken to vary as the inverse square root of the distance from the exciting star. The optical depth of the region of formation of the grains was four times that of the mean sample data of Fig. 2. The points represent the observational data of Gillett and Forrest⁸ and of Merrill *et al.*⁹.

reduction in 3 μm opacity by a factor ~ 1.3 already exists between native cotton cellulose and mercerised cotton, studied by O'Connor³.

Astronomical observations also show minor shifts in the central wavelength of the 3 μm absorption dip with transmittance minima in the range 2.9–3.05 μm compared with minima in the range 2.8–2.9 μm for the laboratory systems we have considered. Wavelength shifts of this magnitude could arise for interstellar polysaccharides due to several effects: variations in the extent of hydrogen bonding between chains, particularly if individual chains are separable; effects of attached side

Fig. 4 Required excess opacity (transmittance) in 9–12.5 μm waveband compared with a normalised spectrum of C_3H_6 (propene). The normalisation involves multiplication of the opacities τ in the two cases by factors which equalises the 11 μm transmittance values in the two cases. Observed $\exp -\Delta\tau$ (---); normalised spectrum of C_3H_6 (—).

groups in the polysaccharides; and particle size effects if grains grow to sizes larger than 10^{-5} cm.

(2) The astronomical data require an additional source of opacity in the 9–12.5 μm waveband which must be superimposed upon the polysaccharide transmittance spectrum. This is precisely the waveband where many carbon stars show an excess emission^{4,5} peaking at $\sim 11 \mu\text{m}$ which is readily explained by the presence of a mixture of hydrocarbons. The excess transmittance $\exp(-\alpha \Delta\tau)$ for our dashed curve in Fig. 2 is shown in Fig. 4. The constant α is chosen appropriately for comparison with a suitably normalised laboratory transmittance spectrum⁶ for propene (C_3H_6). The normalisation arbitrarily equalises the value of the transmittance at 11 μm in both cases. The remarkably close agreement leads us to infer the presence of a similar material which is apparently closely associated with interstellar polysaccharides. Hydrocarbons of this type may be produced as an intermediary in the building process of polysaccharide chains in sources, and also as a result of a partial degradation (similar to a coalification process) of polysaccharides in interstellar space.

Change in nature of stratospheric aerosol collected at 34°S

AEROSOL collected from the stratosphere at Mildura (34.2°S, 142.1°E) has undergone a marked change in character after a period of about seven years with little variation. During the period 1970 to February 1977 aerosol collected by jet impaction at altitudes up to about 28 km has predominantly been sulphuric acid, except for a brief period in January 1972 when particles with a wide variation in morphology were observed¹. The change reported here indicates a substantial incursion of ammonia into the stratosphere, sufficient to almost completely convert the sulphuric acid to one of the ammonium salts, either NH_4HSO_4 or $(\text{NH}_4)_2\text{SO}_4$.

Increased ammoniation is indicated principally by the change in morphology of particles collected (during ascent) on a carbon surface and 'shadowed' with silicon oxide later in the laboratory. The sequence is shown in the T.E.M. photographs in Fig. 1a, b and c. The flights are: a, fl. 667, 2 February 1977; b, fl. 672, 28 April 1977; c, fl. 675, 1 July 1977. The particles shown in Fig. 1 were all collected near 18 km altitude but are in fact representative of the overall aerosol layer between the altitudes of about 16 and 28 km. Particles from flight 667 consist of a small central spherical cap surrounded by rings of acid droplets. This is typical of the aerosol collected over the past seven years and also of aerosols generated from H_2SO_4 in the laboratory and indicates a large proportion of free sulphuric acid in these aerosols. On the April flight, the relative increase in size of the central particles and their 'eroded' appearance points to an increase in ammonia content, while particles collected on the July flight (Fig. 1c) clearly show the morphology of ammonium sulphate with only a very small acid component, that is a flattish eroded dome with a few surrounding droplets. Many of the particles collected at a higher altitude on this flight were found on examination to be in a crystalline form, recognisable as $(\text{NH}_4)_2\text{SO}_4$.

The changed appearance of etch marks left by particles impacted on a copper surface and then subjected to a humid atmosphere is another indication of the changed nature of the aerosol, although this change is non-specific.

Clear etch marks typical of sulphuric acid are evident only on flight 667 (Fig. 1d) whereas the later flights, particularly 672, show a 'splashed' appearance, suggesting a moist or semi-liquid reactive aerosol (Fig. 1e and f).

Chemical testing by thin film techniques with BaCl_2 (refs 2, 3) a specific test for sulphate, shows that for all three flights sulphate is present as a major component in all particles within the radius range of approximately 0.03 to 1 μm (see Fig. 1g, h and i).

Neither the latitude of the NH_3 injection nor the mechanism of its transport into the stratosphere is known. If, however, we use mass loadings calculated from a flight that closely preceded the change a rough estimate of the quantity of NH_3 required to neutralise the H_2SO_4 present can be made. The concentration of particles observed by *in situ* photoelectric counting of individual particles on the flight of 12 November 1976 (J. E. Laby, unpublished) and the size distribution derived from our impaction studies yield a mass of 1.1×10^{-10} kg of H_2SO_4 in a 1 cm^2 column between the tropopause at 12.9 and 30 km. To neutralise this fully to $(\text{NH}_4)_2\text{SO}_4$ requires 3.7×10^{-11} kg of NH_3 , equivalent to a uniform mass mixing ratio of 2.3×10^{-10} . Distributed uniformly over the hemisphere the total mass involved would be a prodigious 10^8 kg. We may, therefore, assume until observations from other latitudes are available that the phenomenon was relatively local. Nevertheless, a very large total mass of ammonia

Fig. 1 Particles collected by impactation at approximately 18 km on *a*, 2 February; *b*, 28 April and *c*, 1 July 1977. Surface morphology is shown in the top row which shows particles caught on carbon surfaces and later 'shadowed'. A clear change from H_2SO_4 on the left to $(\text{NH}_4)_2\text{SO}_4$ on the right can be seen. The reactions of particles with a copper collection surface are shown in the centre row and in the bottom row the insoluble BaSO_4 precipitate rings which form after post-coating collected particles with a thin film of BaCl_2 and humidification indicate the presence of sulphate ion.

must have been involved, and it was certainly the most significant injection of the last seven years.

The observations reported here also reveal a phenomenon of particular relevance to stratospheric monitoring: an almost complete change in the nature of the aerosol which simply could not be determined with present remote optical sensing techniques. Direct collection of particles and examination by electron microscopy must remain an essential method of interpretation of stratospheric particulate sources and processes.

Predicting concentrations in plumes subject to dry deposition

THE source depletion¹ estimation of dry deposition from the atmosphere is less accurate than the physically more correct surface depletion method^{2,3}. Several surface depletion models^{2–9} have been developed but the source depletion method is still used^{1,10}. The errors introduced by using the latter might have important consequences for assessing the impact of deposition from anthropogen sources. Only the recent^{4–6} studies discussed here quantify the discrepancy between the two deposition

methods. We suggest that a ratio R , based on a representative measure of the eddy diffusivity, plume height, and the deposition velocity, should be used to discriminate between cases where the source depletion method introduces significant errors and those where the difference between the two methods is negligible.

Vertical dispersion and dry deposition of material from low sources can be treated in a physically acceptable way by the dispersion equation based on gradient transfer theory (K -theory)¹¹. Gravitational forces are usually neglected and only eddy turbulent transport is considered in the vertical direction. These assumptions are relevant for gases with approximately the same density as ambient air and for submicron particles. Larger particles must be treated separately.

If the dry deposition is discounted, simplified solutions of the diffusion equation lead to the Gaussian dispersion model, which is easy to handle and compare with experimental results, such as tracer studies. Deposition is easily accounted for by reducing the effective source strength as a function of distance. In this 'source depletion model'¹, the vertical concentration profile remains Gaussian and unchanged by the deposition at ground.

An alternative is to solve the dispersion equation with a flux boundary condition at the ground in agreement with gradient transfer theory¹²:

$$\{K(z) \partial c / \partial z\}_{z=z_g} = V_d(z_g) C(z_g)$$

where c is the concentration, z the height, $K(z)$ the eddy diffusivity as function of height, V_d the velocity of deposition and z_g the height of the reference surface. Solution of the dispersion

Neutral	70	2.50	4.0	190	4.00	2.0	210	4.50	2.0
Stable	25	0.05	0.2	60	0.10	0.2	75	0.15	0.2

H is effective plume height, K is the average diffusivity in the layer, and R is the discrimination ratio.

equation with this requirement results in a 'surface depletion model'^{8,9}, where the vertical concentration profile is modified by the loss of material at the ground. The decreased concentration at the ground in the surface depletion model, verified by experiments^{2,3}, results generally in decreased deposition, compared with the source depletion model.

A recent Gaussian surface depletion model⁵ shows that the source depletion model consistently overpredicts the surface air concentration and the deposition at downwind locations close to the source, and is consequently biased in the opposite direction for locations far from the source. The largest differences appear for low sources in stable stratification over surfaces with relatively large deposition velocities. Some parameters were found to be in error by factors of 3–4 at downwind distances of 10 km (ref. 5).

One-dimensional surface depletion models have been used for long distance travel^{3,6,7}. Considering the amount of airborne material after one day's travel during neutral stratification and with a deposition velocity of 3 cm s^{-1} , the source depletion model underestimates the total amount of airborne material by a factor of 10 compared with this surface depletion model⁶.

Studies with a two-dimensional pseudo spectral surface depletion model⁴ using physically realistic diffusivity and wind profile showed that the latter is important close to the source. Figure 1 shows the suspension ratio, that is the ratio between the vertical integrated airborne mass computed with and without deposition as a function of distance from a continuous point source at a height of 25 m. In the unstable (a) and neutral (b) case, the source and surface depletion models do not deviate significantly. The stable (c) case shows that the surface depletion model yields a lower suspension ratio than the source depletion model at distances $< 6 \text{ km}$ while the opposite is the case at larger distances. Further details on these studies will be published elsewhere⁴.

These results indicate that the deposition close to the source is underestimated and, in general, overestimated at medium distances with a source depletion model. But if a plume is dispersed in stable stratification and, at a distance of 20–30 km from the source, disperses to the ground due to, for example, mechanical turbulence and buoyancy induced by an urban area, the deposition is underestimated by the source depletion model by a factor close to 2. These results might be important for assessment of safety around industrial, such as nuclear, installations.

The deposition velocity used here: $V_d = 1 \text{ cm s}^{-1}$ is an average value for SO_2 . Submicron particles, such as sulphate-containing particles, deposit with an approximate velocity of one order of magnitude lower^{13,14}. The diffusivity profiles are relevant for rural country, while the diffusivity, for example, over cold water surfaces, is significantly decreased because of small aerodynamic roughness and cooling at the surface¹⁵. In general, both diffusivity and deposition velocity are functions of surface characteristics and meteorological conditions¹⁴.

The error introduced by the source depletion method is determined by the ratio between the eddy turbulent resistance and the resistance represented by the deposition velocity. A depth L can be determined by the ratio between an effective eddy diffusivity K , and the deposition velocity: $L = K/V_d$, where K is the average diffusivity over the depth H of the atmosphere containing the dispersed material. At large distances from the source, H is equal to the mixing height. At

small distances, $H \approx h + \sigma_z$, where h is the effective source height and σ_z is the standard deviation of the concentration distribution in the vertical direction.

If $L \approx H$, the resistance of the eddy transport is comparable to the deposition resistance, and a source depletion model will not introduce significant errors. This is shown to be the case in neutral and unstable atmospheric conditions with $V_d = 1 \text{ cm s}^{-1}$ (see Fig. 1 and Table 1). During stable atmospheric conditions, L becomes much smaller than H , and a surface depletion model should be used in order to avoid significant errors. A discrimination ratio $R = L/H$ is evaluated on the basis of present studies⁴ (Fig. 1 and Table 1). R can be interpreted as the ratio between a characteristic time for depletion of the depth H of the atmosphere by deposition $\sim H/V_d$, and a characteristic time for diffusion over the same distance $\sim H^2/K$; R is a function of source height and distance. Thus R should not be confounded with the turbulent Sherwood number of vertical surface layer mass transfer. Our studies show that only if $R > 1$, can the source depletion method be applied without significant

Fig. 1 Computed suspension ratio as function of distance from a source at a height of 25 m above ground. Solid line gives the values from a surface depletion model. Broken line gives the values from a source depletion model. Large discrepancies are seen only under the stable atmospheric conditions. a, Unstable; b, neutral; c, stable.

errors, while the surface depletion method can be applied for all values of *R*. This relation has not been previously taken properly into account^{1,10}.

Chemical pretreatment
and radial flow of ¹⁴C in tree rings

THE prospect of very large increases in atmospheric CO₂ concentrations by fossil fuel combustion during the next century has prompted an active interest in CO₂ levels of the last century. One way of measuring these concentrations is by doing precise ¹⁴C determinations in wooden tissue of known age. The first question to be answered, then, is whether wood grown during a certain year truly reflects atmospheric ¹⁴C levels of that year. And if whole wood does not, what chemical treatment has to be given to it in order to isolate those substances that do reflect atmospheric ¹⁴C at the time of formation of the ring. Attempts to answer this question have been made but the only conclusion that investigators^{1–5} generally agree on is that all resin fractions are to be distrusted and that the amount of contamination by material from other years of growth depends on tree species. But in some cases resin extraction by organic solvents does not seem to be sufficient^{1,2}. Having installed a new high precision ¹⁴C counting system, to be described elsewhere, we looked at this question again, in view of our further tree ring measurements and the chemical treatment to be applied to our samples. We found that in the tree studied, an oak, radial movement of ¹⁴C across ring boundaries is minor, even where the heartwood–sapwood transition takes place. If year to year

Fig. 1 Δ¹⁴C in atmospheric CO₂ of the northern hemisphere. This figure is a compilation of atmospheric ¹⁴C measurements carried out by Nydal, Vogel and Olsson during 1962–1963. Δ¹⁴C of wood cellulose (arrows) is compared with values from Farmer and Baxter¹, the lower arrows in both years referring to Farmer and Baxter.

variations are small, the effect is negligible. Furthermore, cellulose and wood, treated successively with hydrochloric acid, sodium hydroxide and again hydrochloric acid, both seem acceptable for monitoring past ¹⁴C levels, although they may not exactly refer to the same time of year.
Extensive hydrogen bomb testing raised the ¹⁴C level of the northern hemisphere some 40% from 1962 to 1963. If any ‘radial flow’ of ¹⁴C between successive tree rings exists, the effect is expected to emerge clearly in these year rings. We, therefore, selected wood from these years from the stem of an American oak (*Quercus rubra*), grown in the rural area of the province of Drente, the Netherlands (52° 45’ N, 6° 50’ E) that was felled by a severe storm in November 1972. In this tree the heartwood–sapwood transition took place in the rings of 1961–64.
Four different modes of chemical pretreatment were applied: (1) no pretreatment, that is combustion to CO₂ of whole wood; (2) treatment with 4% HCl at 80 °C during 24 h; (3) treatment with successive 4% HCl (80 °C, 24 h), 4% NaOH (80 °C, 24 h), and 4% HCl (80 °C, several hours), each step separated by thorough washing with demineralised water. This treatment is

AS 1962	GrN-8063	AAA	150	59	−25.02	401.3±1.6
AS 1962	GrN-8100	Acid	148	81	−25.41	412.6±1.6
AS 1962	GrN-8099	Whole wood	91	91	−26.03	409.4±1.6

routinely applied to most organic samples in our laboratory (AAA treatment); (4) preparation of α -cellulose, successively obtained by extraction with a 2:1 mixture of benzene-ethanol during several hours, rinsing with ethanol, bleaching by a NaClO_2 solution and acetic acid⁸, followed by treatment with 4% NaOH (80 °C, 24 h) and 4% HCl (80 °C, several hours). The last three steps again are separated by washing with demineralised water.

Before using methods (2), (3) or (4) the wood has to be chipped to matchstick size. The size of the final samples as they are measured is 50–55 l of CO_2 gas at NTP. The samples were kept under high pressure in small stainless steel containers. Therefore, special care had to be taken that the tiny amount of gas needed for ^{13}C determination had not undergone isotope fractionation with respect to the bulk of the sample. The results are given in Table 1 and plotted in Fig. 2, together with the results of Farmer and Baxter¹. The $\Delta^{14}\text{C}$ values are obtained by

$$\Delta^{14}\text{C} = ((A_s - 0.95 A_{ox}) / 0.95 A_{ox}) \times 1,000$$

where A_s and A_{ox} are the age and fractionation corrected ^{14}C activities of the sample and oxalic acid (samples to $\delta^{13}\text{C} = -25.0\text{‰}$, oxalic acid to -19.0‰).

Fig. 2 $\Delta^{14}\text{C}$ in tree rings after different chemical pretreatments. The small error bars refer to this paper the larger to Farmer and Baxter¹: ● Whole wood; ■ cellulose; □ acid; ▲ AAA; ○ acetone; ● acetone-petrolether; × lignin; △ acid-alkali; ● acetone-acid-alkali.

The $\Delta^{14}\text{C}$ of whole wood from 1962 is 20‰ higher, that from 1963 15‰ lower than the respective cellulose fractions. With regard to a difference between the atmospheric ^{14}C levels in these years of about 400‰ this points to a 4–5% 'mixing' of organic material, presumably resins, across the 1962–63 boundary. Compared to the AAA pretreatment these figures are +10‰ and –25‰ respectively. Treatment with acid does not change this picture much. The AAA sequence, however, gives a result which is about 10‰ higher than cellulose both in 1962 and 1963 and when another, arbitrary ring was tried:

$$\begin{aligned} 1971 \text{ cellulose } \Delta^{14}\text{C} &= +496.4 \pm 2.8\text{‰} \quad \Delta^{13}\text{C} = -23.88\text{‰} \\ 1971 \text{ AAA } \Delta^{14}\text{C} &= +512.5 \pm 3.6\text{‰} \quad \Delta^{13}\text{C} = -25.27\text{‰} \end{aligned}$$

An explanation for this could be that the AAA treatment attacks earlywood more than it does latewood. The stratospheric leak occurring each year at our latitudes causes ^{14}C levels to be much higher in August than in early spring, at least several per cent during the 1960s. An alternative explanation is that the AAA treatment does not remove lignin or its fragments. Lignin is added to the cell structure in later stages of cell growth⁷. Full lignification of cells in *Pinus ponderosa*, for instance, occurs about a month later than cellulose formation. This hypo-

thesis is supported by the $\delta^{13}\text{C}$ values found, as lignin generally is more depleted in ^{13}C than cellulose. Also Wilson and Grinsted⁸, in searching for climatic information from stable isotopes in very thick tree rings, have found a displacement in time of the lignin curve against the cellulose curve.

Furthermore, Fig. 2 shows that Farmer and Baxter's $\Delta^{14}\text{C}$ values are consistently lower than ours. Cellulose for instance is $12 \pm 7\text{‰}$ lower in 1962 and $83 \pm 8\text{‰}$ lower in 1963. This cannot result from a latitudinal effect, as Nydal has shown it to be virtually non-existent⁹. Moreover, their tree has grown at almost the same latitude (Glengarry, Scotland, 57° N) as ours. Both trees grew in rural environments. In our view, the observed effect follows either from a shift in time of major growth, that is, the Glengarry tree grew earlier during the year than the Drente tree, or local recycling of CO_2 is involved, that is, the incorporation in the ring of CO_2 from decaying organic matter in the forest. The rate of increase of atmospheric ^{14}C levels was 40‰ per month and 90‰ per month until August in 1962 and 1963 respectively (Fig. 1). This observation supports the first hypothesis but does not exclude the second. The second hypothesis is supported by the fact that the Drente tree was planted in 1880 and did not grow in a forest, while the Glengarry tree was only planted in 1937 in a forest.

Unusual room temperature afterglow in some crystalline organic compounds

STRONG room temperature phosphorescence studies of certain doped solid systems^{1–4} have shown that the characteristic phosphorescence peak wavelengths agree with those established for the corresponding dopants dissolved in 77K systems; the room temperature lifetimes being smaller by a factor of 1.5–2, depending upon the nature of the matrix. We have recently observed an unusual new phenomenon—a weak afterglow from certain of the dopant compounds including carbazole, dibenzothiophene, dibenzofuran and triphenylene when examined as pure crystalline solids. This weak afterglow has different peak wavelengths and lifetimes, but in dilute solid solution form in room temperature resin systems there is no trace of the weak afterglow properties. Melting and resolidification of these pure aromatic compounds do not affect the weak afterglow, and, after vacuum sublimation of carbazole, the afterglow is still observed from the purified product. We believe that we can rule out an impurity effect and this view is reinforced as the afterglow intensifies after recrystallisation from ethanol. As the crystals probably improve on recrystallising, the crystal quality may play a role in this phenomenon.

The phosphorescence spectrum of a dilute (1%) solid solution of carbazole in a thermoset resin at room temperature is shown in Fig. 1b (recorded using an EMI

Fig. 1 *a*, Room temperature afterglow spectrum of crystalline carbazole. *b*, Phosphorescence spectrum of 10^{-2} Molal solid solution of carbazole in a thermoset resin at a gain factor of 0.05 relative to *a* at the same setting of the spectrophosphorimeter.

photomultiplier type 6256). The main peaks at 420, 450 and 469 nm correspond well with the phosphorescence emission peaks in *n*-heptane at 77K (ref. 5). The room temperature lifetimes of the 420 and 450 nm peaks are 3.8 and 4.85 s respectively, which is a reduction by a factor of 2 compared with the 77K system. The weak afterglow spectrum is also shown in Fig. 1*a*, at a gain factor of 20 for 100% solid crystalline carbazole at an identical setting of the spectrophosphorimeter. This spectrum shows peaks at approximately 430 nm and also at 522, 552 and 568 nm wavelengths. The 430 nm peak has a decay time which is faster than the chart recorder response, 0.3 s. The other peaks at 552 and 568 nm show mean lifetimes of 0.7 and 0.88 s respectively. Figure 2*b* shows log intensity, plotted against time for the strong 450 nm room temperature phosphorescence of the carbazole solid solution in resin and Fig. 2*a* shows the corresponding curve for the weak afterglow peak at 552 nm. As the plot for the weak afterglow is a straight line, it is possible that the weak afterglow, having a first-order decay, has origins in a metastable state, as does the normal 450 nm triplet.

Fig. 2 Plots of $\ln I$ against time. Plot *a* for 552 nm peak of afterglow (see Fig. 1 *a*); *b* for 450 nm phosphorescence peak (see Fig. 1 *b*).

Figure 3*a* shows the total emission spectrum of crystalline carbazole, which is mainly fluorescence, with a negligible phosphorescence above 500 nm. The totally fluorescent emission spectrum of a 10^{-2} Molal solid solution of carbazole in PMMA is shown in Fig. 3*b* (both curves were recorded as observed with an EMI photomultiplier type 9524B). Figure 3*a* for crystalline carbazole, was recorded at half the slit width used for Fig. 3*b*, giving the latter curve a gain factor of times 2. The excitation for both spectra was achieved by the 312 nm mercury lamp line through a grating monochromator. Comparing the curves, Fig. 3*b* for the solid solution shows emission typical of molecular carbazole in dilute solutions in solvents such as ethanol and cyclohexane, apart from some self-absorption at the shoulder at 343 nm (ref. 6). Figure 3*a* for crystalline carbazole, however, has a much broader peak which is red-shifted by 67 nm compared to the higher peak of curve *b* and, in addition, curve *a* does not show any well defined vibrational structure in contrast to the other three emission curves shown in Fig. 1 and Fig. 3*b*. We note that although the fluorescence peak intensity at 423 nm in Fig. 3*a* is about 2 or 3 orders stronger as compared with the afterglow peak intensity at 430 nm in Fig. 1*a*, the peak shapes and position are very similar in both cases. This result indicates that the 430 nm peak in the weak afterglow spectrum has origins from emissive states electronically similar to those yielding fluorescence in crystalline carbazole.

The characteristic strong room temperature phosphorescence properties of carbazole in the thermoset resin (Fig. 1*b*) shows that this is radiative emission from the triplet state. But from the magnitude of the peak intensity of the room temperature phosphorescence, we suspect that the triplet state may be populated by a donor species. The crystalline form of carbazole, however, shows no blue phosphorescence, indicating that either insufficient numbers of normal triplet states are populated, or that the energy is channelled to lower emissive states responsible for the peaks at 522, 552 and 568 nm (see Fig. 1*a*).

Reappraising the afterglow (curve *a*) and phosphorescence (curve *b*) spectra in Fig. 1, we note that the vibrational spacings of the peaks are similar in both cases. The overall shapes also match each other, apart from a magnitude inversion of the 552 and 568 nm peaks compared to the 450 and 469 nm peaks.

Wavelengths of various peaks and shoulders are listed in Table 1*a*. There is good correlation between the two columns, all peaks in column 1 being red-shifted by approximately 90–100 nm. The peaks at 522, 552 and 568 nm show first-order decay rates of afterglow intensity after the illumination is stopped; however, the lifetime is of an order of magnitude smaller compared to the 450 nm phosphorescence peak (≈ 0.7 s, as opposed to ≈ 4.5 s). These results indicate that the afterglow is due to an emission to S_0 of the monomer or to a vibronically similar ground state. Furthermore, T'_1 (metastable state giving weak afterglow) lies below T_1 , the monomer triplet state (the difference being $\approx 4,106 \text{ cm}^{-1}$). Comparisons of the various peaks and shoulders of fluorescence emission spectra of crystalline carbazole and a 10^{-2} Molal solid solution of the same compound in PMMA are shown in Table 1*b*. Apart from a correlation of the two weak shoulders on the long wavelength tail of the emission, there are great discrepancies in the two spectra. This indicates that the excited state in crystalline carbazole (probably a first excited singlet, S'_1) has facilities for vibronic energy dissipation and, furthermore, the strong emission at 423 nm is unique to the crystalline samples. An explanation for these results could be the presence of dimers in the crystalline carbazole, or the formation of an excimer during photoexcitation. Excimer emission from liquid solution is well known for pyrene⁷

Fig. 3 Fluorescent emission spectra of carbazole. *a*, Crystalline carbazole. *b*, 10^{-2} Molal solution in a thermoset resin at a gain factor of 2 compared to *a*. Excitation for both spectra provided by 312 nm line through a grating monochromator from a high-pressure mercury lamp.

which shows a broader and red-shifted spectrum compared to the pyrene monomer emission. We think that random variations of orientation and spatial variations which may be responsible for such broadening in the liquid state would be inhibited in solid crystalline carbazole. The relatively sharp peaks compared to those for liquid state dimers⁷ in the fluorescence and weak afterglow spectra of crystalline carbazole are thus not altogether surprising.

Our results show, therefore, that the monomer in solid solution exhibits normal emission, corresponding to the first excited singlet state and the first excited triplet state. In the crystalline state of pure carbazole, the corresponding emissions of fluorescence and of weak afterglow are completely different, the fluorescent spectrum being broad and showing little or no vibrational structure, indicating energy dissipation from this excited state. The afterglow spectrum shows the unmistakable vibrational bands of transitions between two relatively stable states. We propose that the weak afterglow emission originates from the triplet state of a dimer or carbazole pair. The fluorescence of the crystalline carbazole would be expected to originate in the excited singlet state of the same species, however, the spectral broadening suggests some excimeric character, implying a less stable pairing in the excited singlet as compared with either a dimer triplet state or a dimer ground state.

Utilisation of soapstone in Labrador by Indians, Eskimos and Norse

MUCH of our knowledge of prehistoric peoples of North America comes from the study of their utilisation of imperishable lithic (geological) resources. In some cases geochemical differences in the origin of a particular lithic material have resulted in trace element differences which can be used to characterise the geological source of this material¹. Both geochemical and archaeological studies indicate that the rare earth element (lanthanide) distributions in soapstone (steatite) can be used to characterise this commonly used lithic material^{2–4}. The rare earth elements (REE) in artefacts from Labrador and Newfoundland, measured by instrumental neutron activation analysis and reported here, suggest that the same soapstone sources have been used by Indians, Eskimos, and Norse at various times over the past 4,000 yr.

Apart from the importance of cultural history in general, Labrador, because of its location at the juncture of the arctic and subarctic zones, has an intriguing prehistory. The environmental and cultural boundaries in this region have been studied as they shifted through time^{5–7}. The Indians and Eskimos who occupied this area at various times utilised soapstone in characteristic ways. For instance, the Indians (Montagnais-Naskapi) who were present in southern Labrador 7,500 yr ago made soapstone plummets (fishing sinkers?) which have been found at Late Maritime Archaic (4,000–3,500 yr BP) sites in central and southern Labrador as well as Newfoundland. Dorset Eskimos (who first appeared in central Labrador from the north about 4,000 yr ago) used soapstone for oil lamps, cooking pots and several types of amulets. These artefacts are found in various Dorset sites from Newfoundland north which range in age from 2,500–1,000 yr BP. Later, in Labrador Eskimo times (500–150 yr BP) soapstone was extensively used for posts and lamps until replaced by European technology. A soapstone spindle whorl, found at L'anse aux Meadows, near the northern tip of Newfoundland, is part of the evidence for this early European settlement in North America^{8–9}. Similar artefacts are common in Norse sites in Iceland and northern Europe.

Soapstone, having discrete and localised sources, could not have been available to all of these groups in one locality. Consequently, trade or travel to secure artefacts or raw materials must have been common within and between cultural boundaries. The small size of most soapstone quarries and the lack of information about quarries during the past century in Labrador makes many of the source locations difficult to find. Nevertheless, matching artefacts from the same, but unknown, quarry does provide valuable information about resource procurement. As each geological deposit of soapstone may have formed under different conditions of contact or regional metamorphism from a variety of older rock types, trace element

concentrations vary considerably between different areas. Having analysed over 50 sources of soapstone in eastern North America, we have shown that each formation can be characterised by its trace element contents^{3,10}. In particular, the rare earth elements ($Z = 57-71$) vary in both absolute and relative abundances. The differences can be shown graphically by plotting the normalised concentration of the particular rare earth element (obtained by dividing its concentration in the soapstone by that found in chondritic meteorites) as a function of atomic number³. The curves (REE patterns) reflect the slightly different geochemical behaviour of these elements which result from differences in ionic radii and in the case of Eu, the ionic charge.

Each geological formation may have rocks which vary considerably in their mineralogies, but if they contain sufficient quantities of talcose minerals (such as talc, chlorite, antigorite, and tremolite), they have the physical characteristics which would have allowed them to be utilised. While we have observed that some of the trace elements (for example, Fe and Cr) do depend upon the mineralogy, it seems that the REE do not. Figure 1 shows three examples of the variations observed in REE patterns for soapstone from a particular geological region. Based upon the analysis of between 5 and 20 samples from these and several other individual geological formations, we conclude that the REE patterns are essentially the same in shape (are parallel) but differ in absolute magnitude. For REE concentrations which are about an order of magnitude greater than the chondritic concentrations, the magnitude of the differences observed between samples is about a factor of 2. When the REE concentrations in a soapstone formation are the same as or lower than the chondritic concentrations, the differences between samples from the same source are larger, differing by as much as a factor of 5, but the patterns are approximately parallel. This gives some insight into how well an artefact might be expected to match a sample from a quarry in order to establish the quarry as the source region.

Matching the REE patterns in soapstone artefacts to the source of the raw material is based on the assumption that the quarry can be located and sampled. Although over 50 different soapstone source regions (varying considerably in size) have been differentiated on the basis of their REE patterns, the analysis of artefacts from eastern North America suggest that others have not been found. This has been a particularly difficult problem because the analysis of over 60 Eskimo and Indian artefacts grouped together, according to their REE patterns, suggest that at least eight soapstone sources were used over the past 4,000 yr. But only four of these have been located. Two quarry areas have been sampled in Labrador, one at Freestone Harbour in the Davis Inlet area south of Nain and the other at Moore's Island near Okak, north of Nain. On the island of Newfoundland the large outcrops at Fleur-de-Lys were sampled, as well as an outcrop a mile from the L'anse aux Meadows site (provided by the Conservation Division of Parks, Canada).

The L'anse aux Meadows quarry is of particular interest as it may have been the source of the Norse spindle whorl (Fig. 2). Other use of the L'anse aux Meadows quarry is indicated by a plummet, from the 4,000 yr old Maritime Archaic Indian site at Rattlers Bight in the Hamilton Inlet region, which also has a matching REE pattern¹¹. This relatively distant source was not the most common one for the Indians in this region as most of the plummets from this site have the same REE patterns, but the pattern does not match any of the quarries sampled. One might assume a more local source. In another Maritime Archaic site further north at Windy Tickle (Davis Inlet) the only two plummets have REE patterns which match a nearby soapstone outcrop at Freestone Harbour.

By 2,600 yr BP the Dorset Eskimo culture had advanced into central and southern Labrador and by 2,000 yr BP, into Newfoundland. Dorset people used some of the same quarries or quarry locations as the earlier Maritime Archaic Indians. The Freestone Harbour soapstone was used extensively in the Nain

and Okak areas between 2,700–1,400 yr BP. Soapstone from the Okak region (Moore's Island) was another relatively local source used extensively by the Dorset Eskimos in the Nain area based upon the matching of REE patterns in bowls to those of the quarry (Fig. 2). There was also the rare utilisation (10% of the samples) of the soapstone from the two quarries in Newfoundland. The problem still remains that nearly half of the 30 Dorset artefacts from central Labrador do not match any of these four quarries.

The method of transmission of information about soapstone quarries within the different Indian and Eskimo cultural

Fig. 1 Chondrite normalised rare earth element (REE) distribution patterns of some soapstone outcrops in Virginia and Crete. The Virginia samples are from the Albemarle–Nelson County region and the two lines (X) give the extremes of the range for 15 different samples analysed. The two lines (●) define the range of 14 samples from a relatively large region in Crete which is assumed to be a single large soapstone formation. The patterns (○) noted as Crete B define the range observed for 13 samples from the Gonia region of Crete. In all cases the other samples are approximately parallel to the curves shown but differ somewhat in magnitude within the range defined by these curves. This gives an indication of what type of variations might be expected for artefacts from a particular quarry.

sequences or between ethnic groups at times of culture area changes is not known. Oral tradition must have been important during periods of continuity, but prehistoric peoples (and Norse as well) must have been keen observers of geology. Prehistoric people of Labrador used many different lithic materials, most of whose source locations are unknown today. It is unfortunate that Western culture replaced native traditions so rapidly and completely before these observations could be recorded. We are now confronted with the difficult task of rediscovering the sources of many culturally important lithic materials for use in studying cultural movement and contact. The use of REE patterns to match artefacts to the geological source of the

Fig. 2 Chondrite normalised REE patterns for two quarries and four artefacts interpreted as originating in these quarries. Quarry L (●) is a sample from a soapstone outcrop in northern Newfoundland near L'Anse aux Meadows and the Norse artefact (■) is the spindle whorl from the L'Anse aux Meadows site. The Indian artefact (○) is a plummet from a Maritime Archaic site at Rattler's Bight in Labrador while the Eskimo artefact (+) is from a rectangular cooking vessel from a Dorset Eskimo site in the Nain region further north. The dashed curves (●) outline the range of three samples of soapstone from outcrops in the Okak region (north of Nain) and the Eskimo artifact (×) is another cooking vessel from the same Dorset site in the Nain region.

soapstone provides an important new tool for the study of lithic resource procurement. Most of the soapstone tested from prehistoric sites to date seems to be from local quarries. The presence of occasional exotic materials argues for the existence of exchange networks maintained by social rather than economic need.

This research was supported by NSF grant 41500. Eskimo and Indian artefacts from the Smithsonian Institution were collected with support from The National Geographic Society 1971–72, and the Smithsonian Research Foundation, 1973–76. L'Anse aux Meadows spindle whorl and quarry samples were obtained through the cooperation of J. C. McCawley, Conservator for Parks, Canada. Freestone Harbour samples were obtained through the courtesy of Saunders of Goose Bay, Labrador, and Moores Island samples from S. Cox and N. Ettlinger. Crete samples were provided by M. Becker.

Inhibition of oesophageal peristalsis in the lobster after chemical stimulation

PREVENTION of hyperphagia by some mechanism is essential to feeding animals. To date relatively few such control mechanisms have been studied in detail. Termination of feeding by internal inhibitory feedback from stretch receptors is documented for *Phormia regina*¹, *Locusta migratoria*², *Chortoicetes terminifera*³ and *Aplysia californica*⁴. Chemosensory adaptation has been suggested for *Phormia*¹ and *Chortoicetes*³, and in *Locusta* activation of foregut stretch receptors will, through a nervous and hormonal pathway, close the terminal pores of chemosensory sensilla on the maxillary palps⁵. We present here evidence showing that stimulation of a pair of oesophageal contact chemoreceptor organs can slow the ingestion rate and terminate feeding in *Homarus gammarus*.

The anterior oesophageal sensors (AOS) were first described in *Homarus* by Allen⁶ and were described in more detail in the crayfish *Astacus leptodactylus* by Orlov⁷ (for a review of the sensory innervation of the foregut of decapod crustaceans see ref. 8). These sensors are bilaterally symmetrical and their cuticular endings are situated in the clefts between the anterior and lateral lobes of the oesophageal/cardiac sac valve (data not shown). Each anterior oeso-

Fig. 1 Scanning electron micrographs of the cuticular modifications associated with the anterior oesophageal sensor. *a*, Grouped endings located in depressions in raised hillocks on the lateral wall of the anterior lobe of the oesophageal/cardiac sac valve. *b*, Single endings present deep in the cleft between the anterior and lateral lobes of the valve. It is possible that the sensilla have terminal pores (arrowed). The single endings bear a marked resemblance to those described for contact chemoreceptors in insects^{9,10}. Scale bar, 10 µm in *a*, 4 µm in *b*.

phageal sensor is innervated by a dorsal branch of the ipsilateral superior oesophageal nerve (SON) and can be divided readily into two populations of receptor neurones; 1, 50–60 bundles of 3–5 small (15–20 μm long axis) uniterminal bipolar neurones; and 2, 250–300 similar small neurones which are present singly. The cuticular modifications associated with the dendrites can be divided similarly (Fig. 1). In addition there are between two and five large (60–80 μm long axis) bipolar neurones whose axons also travel in the anterior oesophageal sensor nerve and whose long dendrites travel over the surface of the cardiac sac and oesophagus in the region of the valve.

Recording and stimulation of selected nerves was carried out with silver wire hook electrodes using conventional techniques. In all experiments the bathing medium was clean, cool seawater. The organ was chemically stimulated with an extract of *Mytilus edulis*. The gills and mantle of a fresh mussel were homogenised in approximately the same volume of seawater. This was applied directly on to the anterior oesophageal sensor with a glass pipette inserted through a hole cut in the cardiac sac. The afferent axons of other chemoreceptors in the area were cut.

The oesophagus undergoes peristalsis for some time after initial dissection, and recordings from the superior oesophageal nerve during this time reveal a complex rhythmical burst which can be shown to occur during oesophageal dilatation. This burst was used as an indicator of oesophageal dilatation during peristalsis. The frequency of bursting is relatively constant at any one time but varies between 0.1 Hz and 0.33 Hz. Suprathreshold electrical stimulation of the anterior oesophageal sensor nerve with a train of rectangular pulses of width 0.6 ms and with a pulse interval of 500 ms has two effects (Fig. 2). In this preparation the burst frequency dropped from its original level (about 0.28 Hz) to approximately 0.1 Hz; this was accompanied by a drop in the number of spikes in each burst. On cessation of stimulation the burst frequency and the number of spikes per burst increased but did not reach their original level. Application of *Mytilus* extract directly on to the anterior oesophageal sensor mimics the effect of electrical stimulation of the sensory axons by reducing the burst frequency (Fig. 3), although there is no reduction in the number of spikes per burst. Continued application can terminate bursting, and to be effective the extract must be closely and continuously applied.

The anterior oesophageal sensors are classified as contact chemoreceptors on morphological grounds and direct ex-

Fig. 2 Effect of electrical stimulation of the anterior oesophageal sensor nerve (black bar) on rhythmical bursting in the SON. The number of spikes in each burst (a) and the burst frequency (b) are plotted against the time of occurrence of each burst. Burst frequency is calculated as the reciprocal of burst interval which is measured from the start of one burst to the start of the succeeding burst.

Fig. 3 Effect of chemical stimulation of the anterior oesophageal sensor on rhythmical bursting in the superior oesophageal nerve. (a) and (b) are different experiments. Application of *Mytilus* extract (solid arrow) slows and stops bursting (a). In (b) burst frequency increases on removal of the pipette (open arrow) but without washing the organ.

perimental evidence is not yet available. The positions of the receptor organs are such that they become available for stimulation only when the cardiac sac is filled to capacity and the oesophageal/cardiac sac valve is stretched open. The solitary endings lie deep in the cleft between the lobes of the valve while the grouped endings spread on to the lateral walls of the anterior lobe. It is unlikely that these positional differences reflect functional differences, the more complex arrangement of the grouped endings probably serving to prevent causal stimulation during feeding. The observed difference between electrical and chemical stimulation can be explained by the presence in the anterior oesophageal sensor nerve of the axons of the small group of large bipolar neurones. These are presumptive mechanoreceptors that may respond to stretch in the region of the oesophageal/cardiac sac valve and could also be involved in the control of the peristaltic rhythm.

These observations suggest an alternative control mechanism for feeding processes, dependent upon chemical rather than mechanical feedback to higher centres. It is possible that such methods of controlling food ingestion will be found more commonly, especially amongst decapod crustaceans.

A *Rhizobium* mutant incapable of nodulation and normal polysaccharide secretion

THE surface carbohydrates of *Rhizobium*, including both the lipopolysaccharide and the extracellular polysaccharide, are thought to participate in the infection and nodulation of legumes by these Gram-negative bacteria^{1–3}. We report here the isolation of a mutant of *Rhizobium leguminosarum* which produces diminished amounts of extracellular polysaccharide

(that is, the carbohydrate material present in cell-free filtrates of bacterial cultures) and which fails to nodulate pea, its normal host.

Two antibiotic resistance markers were introduced, by spontaneous mutation, into *R. leguminosarum* strain 128c53 (obtained from J. C. Burton of Nitragin Co.). Approximately 10^{10} cells of this strain growing in minimal liquid medium⁴ were concentrated by centrifugation. The cell pellet was resuspended in 0.1 ml of medium and spread on a minimal agar plate⁴ containing 100 µg of streptomycin sulphate per ml. A single colony arising on this medium was purified twice by streaking minimal medium plus streptomycin. This streptomycin resistant (*str*) derivative of 128c53 was then grown in liquid medium, concentrated, and spread on solid, defined medium containing 100 µg streptomycin and 20 µg rifampicin per ml. A purified single colony resistant to both streptomycin and rifampicin (*rif*) was checked for its ability to nodulate pea seedlings. This *str* and *rif* derivative of 128c53 was then used to isolate five strains of bacteriophage (differing in plaque morphology) from a mixture of mid-western soils according to the procedure of Vincent⁵.

Spontaneously arising mutants of *R. leguminosarum* 128c53 *str* and *rif* which produce decreased amounts of extracellular polysaccharide were obtained by passing late stationary phase cultures of this strain through 1.2-µm Millipore filters, adding an equal volume of fresh medium, and allowing the cells to grow into late stationary phase again. This process was repeated four times over approximately 30 d. These bacteria were then diluted and spread on solid media to observe colony morphology. Over 90% of the colonies arising on such plates were small and seemed to lack the heavy slime produced by the starting strain, 128c53 *str rif*. Seven of these small colonies were purified and examined further.

Table 1 Extracellular polysaccharide production by *R. leguminosarum* 128c53 *str rif*, by EXO-1, and by a revertant of EXO-1, EXO+ 4

Strain	Carbohydrate produced (glucose equivalents ($\text{g} \times 10^{-12}$) per viable count)
128c53 <i>str rif</i>	32.0
EXO-1	1.14
EXO+ 4	31.0

Cells were shaken for 6 d in liquid medium⁴ at 24 °C until a density of approximately 10^8 ml⁻¹ was obtained. Viable counts were then determined by plating appropriate dilutions on solid agar medium⁴. Extracellular material was prepared as follows. Cultures were centrifuged for 30 min at 10,000 r.p.m. The supernatant solutions were passed through 5-µm Millipore filters and then concentrated under reduced pressure and at 40 °C to give one-tenth of the original volumes. The concentrated supernatant solutions were dialysed and lyophilised. The resulting powders were dissolved in 0.2 M imidazole buffer, 0.1 M NaCl, pH 7, and assayed for carbohydrate content by the anthrone method⁶.

Bacteria from all seven small colonies were resistant to streptomycin and rifampicin and sensitive to bacteriophage 1-5 (see above). The strain producing the smallest colonies, designated EXO-1, was chosen for further study.

EXO-1 has a doubling time, both for viable counts and optical density, identical to its parent *R. leguminosarum* 128c53 *str rif* (data not shown). This indicates that EXO-1 does not produce small colonies due to a defect which slows its growth. Extracellular carbohydrate was determined as described in Table 1. On a per cell basis, EXO-1 culture filtrates contain approximately 5% of the amount of anthrone-positive material present in culture filtrates of 128c53 *str rif*. EXO-1 and four similar mutants derived from 128c53 *str rif* by the procedure described above were used to inoculate pea seedlings (Table 2). All five of these strains failed to nodulate Alaska pea.

Indirect evidence suggests that the lipopolysaccharide component of the cell wall of *Rhizobium* may be involved in

Table 2 Nodulation tests

EXO+ 3	230
EXO+ 4	220
EXO+ 5	240

All values are the average of at least three separate experiments, each of which contained at least three plants. Peas were surface sterilised by treatment with 70% ethanol for 5 min followed by treatment with 30% hydrogen peroxide for 30 min. These surface-sterilised peas were soaked overnight in sterile Fahraeus solution⁷ and then planted in sterile vermiculite. The plants were grown using a 14-h light/10-h dark cycle at 22 °C day temperature and 18 °C night temperature. Illumination was 2,500 foot candles. Bacteria were grown to a density of approximately 10^8 ml⁻¹ (ref. 4) by shaking at 24 °C. Cultures were then centrifuged and resuspended in an equal volume of distilled water. Ten-day-old Alaska pea seedlings were inoculated with 10 ml of these bacterial cultures. The roots of these plants were inspected 18 d later. Extracellular polysaccharide producing revertants of EXO-1 were obtained by spreading approximately 10^6 cells of this strain on minimal agar plates⁴. Slime-producing colonies, which arose on these plates at a frequency of approximately 10^{-5} , were isolated and purified.

host-symbiont selection². We therefore examined the lipopolysaccharide of EXO-1 to determine whether this cell surface component is altered by the mutation which reduces extracellular polysaccharide production in this strain. By three criteria, the lipopolysaccharide of EXO-1 seems very similar, if not identical, to that of its parent, 128c53 *str rif*. First, as mentioned above, EXO-1 and 128c53 *str rif* are sensitive to the same bacteriophage. Since most receptors for bacteriophage are located in the lipopolysaccharide⁸, the similarity of phage

Table 3 Glycosyl composition* of the lipopolysaccharides of *R. leguminosarum* 128c53 and 128c53 *str rif* EXO-1

Sugars	<i>R. leguminosarum</i> strains	
	128c53 %	128c53 <i>str rif</i> EXO-1 %
Rhamnose	24	21
Fucose	33	27
Mannose	18	23
Galactose	4	3
Glucose	1	1
2-amino-2, 6-dideoxyhexose	2	3
Uronic acid	14	14
KDO	10	8

Aldoses and amino sugars were analysed as their alditol acetates. The lipopolysaccharides were hydrolysed for 60 min at 121 °C in 2 M trifluoroacetic acid. The resulting monosaccharides were converted to their corresponding alditol acetates and analysed by combined gas chromatography-mass spectrometry¹². 2-Keto-3-deoxyoctanoic acid (KDO) was determined using the thiobarbituric acid colorimetric assay¹³ with the ammonium salt of KDO (Sigma) as the standard. Uronic acid was determined using the *m*-hydroxybiphenyl assay¹⁴ with galacturonic acid as the standard.

*The sugar composition is given as per cent of total sugar. In strain 128c53, the total sugars account for 63% of the lipopolysaccharide mass. In 128c53 *str rif* EXO-1, the sugars account for 27% of the lipopolysaccharide mass.

Fig. 1 Immunochemical analysis of the lipopolysaccharides from various *Rhizobium* strains. Antisera (centre well) prepared against the lipopolysaccharide purified from *R. leguminosarum* 128c53 forms a precipitin band when diffused against the lipopolysaccharide from this strain and when diffused against the lipopolysaccharide from its extracellular polysaccharide deficient derivative, EXO-1. The antisera does not cross-react with lipopolysaccharide purified from another strain of *R. leguminosarum* or with lipopolysaccharide purified from a strain of *R. phaseoli*. Each well contains 15 μ l of a 2 mg ml⁻¹ solution of the indicated lipopolysaccharide. In general, the lipopolysaccharides prepared from *Rhizobium* are immunochemically strain and species specific (ref. 9 and R.W.C., C. Napoli, R.E.S. and P.A., in preparation). Lipopolysaccharides were prepared as previously described² with the following modification. The aqueous phase of a phenol-water extract of *R. leguminosarum* 128c53 is viscous and must be ultracentrifuged at 100,000g for 3 h before use of the Agarose A 1.5m column. The other lipopolysaccharide preparations were not as viscous and were purified without the ultracentrifugation step. Before the ultracentrifugation or passage through sizing columns, the lipopolysaccharide preparations were incubated overnight (17 h) at room temperature with 1 mg each of DNase I (Sigma) and RNase A (Sigma) to depolymerise the nucleic acids. The final lipopolysaccharide preparations do not have a λ_{max} between 230 nm and 320 nm and form typical opalescent solutions when dissolved in water at a concentration of 1 mg ml⁻¹. Antiserum to *R. leguminosarum* 128c53 was prepared as previously described^{9,10}. Micro double diffusion tests were performed as described by Crowle¹¹. The diffusion plates (microscope slides) were prepared with 0.75% Noble agar (Difco) in 10 mM sodium phosphate and 0.85% NaCl, pH 7.0. The diffusion tests were allowed to develop for 48 h at 4 °C before being submerged overnight at room temperature in a solution of 10 mM sodium phosphate and 500 mM NaCl, pH 7.0. The plates were then agitated in distilled water for 30 min and stained for 15–30 min in a solution composed of water: isopropanol: acetic acid (13:5:2) containing 0.05% Coomassie brilliant blue R (Sigma). The plates were destained for about 60 min in a solution composed of water: isopropanol: acetic acid (8:1:1).

patterns may be a reflection of lipopolysaccharide structural identity. Second, lipopolysaccharide purified from EXO-1 seems immunochemically identical to lipopolysaccharide isolated from 128c53 *str rif* (Fig. 1). This is particularly pertinent as the lipopolysaccharides of different *Rhizobium* strains are immunologically distinct (R.W.C., C. Napoli, R.E.S. and P.A., in preparation). Finally, the sugar compositions of the carbohydrate moieties of the lipopolysaccharide from EXO-1 and 128c53 *str rif* are very similar as determined by gas chromatography (Table 3).

We have isolated five spontaneous revertants of EXO-1 which have regained the ability to produce copious amounts of extracellular polysaccharide. All five of these revertants have retained resistance to streptomycin and to rifampicin, are sensitive to bacteriophage 1–5, and have regained the ability to nodulate pea seedlings (Tables 1 and 2). In these respects, all five of these revertants seem identical to the starting strain 128c53 *str rif*. It therefore seems likely that a single mutational event is responsible for both the reduced production of extracellular polysaccharide by EXO-1 and the inability of EXO-1 to nodulate pea seedlings.

A simple hypothesis which accounts for the above data is that the reduced production of extracellular carbohydrate by the mutant EXO-1 is related to the inability of this strain to nodulate pea seedlings. Further analysis of EXO-1 and

additional mutants affecting the surface polysaccharides of *Rhizobium* may confirm that, as in other systems^{15,16}, surface polysaccharides participate in the infection of eukaryotes by prokaryotes.

Mutations to increased antibiotic sensitivity in naturally-occurring gonococci

CLINICAL isolation of mutations giving increased drug sensitivity has not been previously reported. The experiments presented here indicate that a significant proportion of clinical strains of *Neisseria gonorrhoeae* contain mutations which result in markedly increased susceptibility to a variety of antibiotics. Previously, Maness and Sparling¹ isolated and characterised mutants (*env*) of laboratory gonococci which had markedly increased sensitivity ('hypersensitivity') to a variety of antibiotics, detergents and dyes. The *env* mutations were phenotypically dominant over, and totally suppressed, low-level nonspecific drug resistance determined by mutations at a locus formerly designated *ery*², but now designated *mtr*³. Both *mtr* and *env* affected the permeability of the cell envelope⁴. Most of the clinical hypersensitive strains are also shown to possess mutations to nonspecific drug resistance, similar to *mtr*, which are suppressed phenotypically. We have studied strains which included 502 random isolates from patients in North Carolina with uncomplicated gonococcal urethritis and cervicitis, as well as selected erythromycin-hypersensitive strains from London (kindly supplied by I. Phillips), and five penicillinase-producing gonococci (four from the Far East, one from Rotterdam).

Sarubbi *et al.*² have shown that *env* mutants are at least four times more sensitive to erythromycin, fusidic acid, crystal violet (CV) and Triton X-100 (Trx) than are wild-type strains. Accordingly, we determined the minimal inhibitory concentrations (MICs) to erythromycin for all isolates, using an agar dilution method⁵. Wild-type strains, without *env* or *mtr*, generally are inhibited by 0.25–1 μ g ml⁻¹ Ery². Clinical isolates with erythromycin MIC \leq 0.12 μ g ml⁻¹ were considered possible *env* mutants, and were further evaluated for sensitivity to fusidic acid, crystal violet and Triton X-100. Isolates hypersensitive to all drugs were studied for the presence of *env* and suppressed *mtr* mutations by genetic transformation, employing standard recipient strains and methods^{6,7}. A hypersensitive clinical isolate was considered to contain a suppressed *mtr* mutation if it was

capable of donating a gene for nonspecific low-level resistance to erythromycin, fusidic acid and Triton X-100 to wild-type strain FA19^a.

Clinical *env* mutants were then further characterised as to the type of *env* mutation they possessed by transformation crosses with laboratory strains BR54 (*env*-3) and BR87 (*env*-2). The *env*-2 and *env*-3 mutations are known to occur at separate sites based on recombination frequencies in transformation crosses². To facilitate genetic analysis of the *env*-mutations, high-level rifampin resistant (Rif^R) mutations were selected from the clinical *env* mutants. DNA prepared from such strains were used to transform BR87 and BR54, selecting separately for Rif^R and Env⁺. The Rif^R transformants served as an internal control of the efficiency of the transformation system. The recombination index² (ratio of Env⁺ to Rif^R transformants) was used to determine the proximity of the clinical *env* mutations to *env*-2 and *env*-3.

Results showed that 54 of 347 strains isolated in 1973 (16%) and 30 of 155 strains from 1976 (19%) were hypersensitive to erythromycin (MIC $\leq 0.12 \mu\text{g ml}^{-1}$). Of 35 of these strains further evaluated, 32 were hypersensitive to fusidic acid ($\leq 0.03 \mu\text{g ml}^{-1}$), crystal violet ($\leq 2 \mu\text{g ml}^{-1}$) and Triton X-100 ($\leq 0.25 \text{ mg ml}^{-1}$), whereas none of 53 evaluated wild-type or erythromycin resistant strains were hypersensitive to any of the other drugs; three of five penicillinase-producing gonococci were hypersensitive to erythromycin, fusidic acid, crystal violet and Triton X-100.

Fifteen of 16 tested hypersensitive strains, including the three penicillinase-producing isolates, donated a suppressed gene phenotypically identical to the previously described *mtr* mutation to wild-type FA19. In a typical experiment, a hypersensitive (erythromycin MIC = $0.06 \mu\text{g ml}^{-1}$) donor transferred to the wild-type (erythromycin MIC = $0.25 \mu\text{g ml}^{-1}$) recipient a gene for low-level ($4.0 \mu\text{g ml}^{-1}$) resistance to erythromycin; all Ery^R transformants were also much more resistant to fusidic acid, Triton X-100 and other drugs. Most phenotypically hypersensitive clinical isolates were therefore genotypically resistant.

Transformation crosses between hypersensitive clinical isolates and the isogenic laboratory strains BR54 (*env*-3) and BR87 (*env*-2) confirmed that most of the clinical hypersensitive isolates were *env* mutants (Table 1). In the initial experiments, donor DNA from the clinical isolates was introduced into BR54 and BR87. Results showed that IP6 recombined with much higher frequency with BR87 (*env*-2) than with BR54 (*env*-3), and thus probably contains an *env* mutation very close to *env*-3. FA3024, as well as the penicillinase-producing isolates FA290 and FA362, recombined with high frequency with BR54 but with only very low frequency with BR87. In other experiments, 11 additional hypersensitive strains behaved like FA3024; thus 14 of 16 studied strains were apparently mutant at a site close to *env*-2. In contrast D1519 recombined with both laboratory strains, as well as IP6 and FA3024, and therefore is apparently mutant at a site distinct from those described previously. Reciprocal experiments in which *rif*-2 derivatives of the isogenic set FA19 (*env*⁺), BR54 (*env*-3) and BR87 (*env*-2) were used as donors, and the hypersensitive clinical isolates as recipients, gave very similar results (Table 1).

We suggest that approximately 15% of random clinical isolates from North Carolina, as well as three of five penicillinase-producing isolates, contain *env* mutations, most of which occur in the same gene as the previously characterised *env*-2 mutation, which has recently been shown to result in altered outer membrane proteins by the method of SDS-polyacrylamide gel electrophoresis (D. Walstad, L. Guymon, & P.F.S., unpublished). Presumably the *env* mutation confers on to these strains some selective advantage which cannot be related to their ability to grow in the presence of antibiotics, as these strains are unusually sensi-

Table 1 Recombination indices (Env⁺/Rif^R) in transformations between clinically-isolated antibiotic-hypersensitive (*env*) gonococci and isogenic laboratory mutants containing known *env* mutations*

Donor strains†	Recipient strains‡				
	BR54 (<i>env</i> -3)	BR87 (<i>env</i> -2)	FA3024 (<i>env</i> -5)	FA290 (<i>env</i> -7)	FA362 (<i>env</i> -8)
IP6 <i>rif env</i> -4	0.006	0.4			
FA3024 <i>rif env</i> -5	0.5	0.0005			
FA290 <i>rif env</i> -7	1.2	0.02			
FA362 <i>rif env</i> -8	1.9	0.03			
D1519 <i>rif env</i> -9	0.7	0.2			
FA19 <i>rif env</i> ⁺	2.0	1.5	2.3	1.2	1.5
BR54 <i>rif env</i> -3	< 0.0001	2.3	1.5	0.9	5.0
BR87 <i>rif env</i> -2	1.2	< 0.0001	0.01	0.0009	0.02

*Recombination index equals the number of Env⁺ transformants ml⁻¹ (selected with erythromycin at a concentration of $0.25 \mu\text{g ml}^{-1}$) divided by the number of Rif^R transformants ml⁻¹ (selected with rifampin at a concentration of $2 \mu\text{g ml}^{-1}$). Results are means of at least two experiments. DNA concentrations were saturating.

†All clinical donor strains (IP6, FA3024, FA290, FA362, D1519) were made rifampin resistant (Rif^R) by purifying spontaneous mutants from plates containing $5 \mu\text{g ml}^{-1}$ rifampin. The isogenic laboratory strains (FA19, BR54, BR87) were made Rif^R by introduction of the *rif*-2 allele by transformation.

‡IP6 and D1519 were not competent, and therefore could not be used as recipients.

tive to antibiotics.

In the laboratory these strains autolyse more readily⁴ and would, therefore, appear to be at a disadvantage. We have, however, noted that with laboratory strain FA19, the *mtr* mutation consistently results in reduced rates of exponential growth in enriched broth cultures, whereas introduction (by transformation) of an *env* mutation into the derivative carrying *mtr*, FA140, results in partial restoration of normal growth rates *in vitro* (Table 2). Similar results occurred with the clinical *env* strain FA3024 and its *env*⁺ derivative FA507. We have no evidence, of course, that similar growth rates occur *in vivo*, and other explanations such as greater mucosal adherence of *env* mutants are conceivable.

In the pre-antibiotic era, tested strains of *Neisseria gonorrhoeae* possessed neither low-level resistance nor hypersensitivity to antibiotics⁵. The pressure of antibiotic usage has selected strains with low-level resistance over the past three decades. The commensurate poorer growth characteristics of some of these mutants, though, might have resulted in selective advantage for subsequent mutations which improved growth and decreased resistance. Paradoxically,

Table 2 Log phase doubling times for *env* and *env*⁺ strains

Strain	Ery MIC ($\mu\text{g ml}^{-1}$)	Doubling Time (min) [†]	P Value [‡]
Isogenic laboratory set*			
FA19 (wild type)	0.25	52.7 \pm 4.66	> < 0.005
FA140 (<i>mtr</i>)	4.0	69.3 \pm 2.97	
BR87 (<i>mtr, env</i>)	0.06	57.4 \pm 5.78	
Isogenic clinical set			
FA3024 (<i>mtr, env</i>)	0.06	49.9 \pm 4.27	> < 0.005
FA507 (<i>mtr</i>)	4.0	76.5 \pm 6.99	

*Parent strain FA19 and its transformation derivatives have been described by Sarubbi *et al.*². Both FA140 and BR87 contain other mutations besides those shown², but the slow growth of FA140 is due almost entirely to the *mtr* mutation (data not shown). The full genotype of the clinical isolates is not known.

†Mean $\pm \sigma$. Cells were grown in GC base broth with added supplements². Growth was at 37°C in 125 ml side-arm flasks which were agitated in a metabolic shaker with 5% CO₂. The amount of growth was determined by optical density on a Klett-Summerson colorimeter (No. 540 filter).

‡Paired Student's *t* test.

antibiotic usage may be selecting gonococci with both greater antibiotic resistance and, indirectly, greater sensitivity.

We thank D. Walstad for assistance, and I. Phillips, C. Thornsberry and E. Stolz for donating strains. This work was supported by a postdoctoral fellowship from the USPHS to B.I.E. and NIH research grant to P.F.S.

Control of microbial surface-growth by density

In synchronous cultures of bacteria, the rate of cell elongation¹ or of envelope synthesis² seems to increase abruptly at a particular age. These and other findings suggest³⁻⁵ that bacterial envelope is formed at a constant rate, possibly by enzymes organised in zones, and that some event in the cell cycle leads to a discrete increase in the amount of enzymes or number of zones concerned. (The actual event involved has been variously identified with initiation of chromosome replication⁴, with termination^{1,5} and with the attainment of a critical cell length⁶.) Growth zones are known to occur in the filamentous fungi⁷. The rate at which these zones are able to add new envelope is limited, and since mass increases exponentially⁸, hyphal density eventually begins to rise; when it reaches a critical value, new zones are formed. Thus density (or indeed the concentration of any product synthesised exponentially⁹) could control the rate of surface growth, and we suggest that such is the case in bacteria.

We postulate a constant rate of surface-area synthesis β that doubles once during the bacterial cycle, d min before division¹⁰. For a cylinder with open ends, the cell volume $V(a)$ at age a is given by

$$V(a) = 2^{m-1} R\beta\tau [1 + (a+d)/\tau - m] \text{ for } a \leq (m+1)\tau - d \\ = 2^m R\beta\tau [(a+d)/\tau - m] \text{ for } a \geq (m+1)\tau - d \quad (1)$$

where τ is the mean doubling time of the cell, R is the radius, and $m \equiv [d/\tau]$. If we define ρ_d as the density of the cell at age $\tau-d$, then

$$\rho_d \equiv (M_d/V_d) = (M_1/R\beta\tau)2^{(C+D-d)/\tau} \quad (2)$$

where M_d and V_d are the mass and volume at age $\tau-d$. Here C and D are the times taken to replicate the chromosome and to complete division processes, respectively¹¹, and M_1 is the (constant) ratio of cell mass to chromosome origins at the time of initiation of replication¹².

There is reliable experimental evidence that R does not vary very much over the cell cycle during steady-state growth¹³. If we take it to be completely independent of a , then

$$\bar{V} = (M_1/2\rho_d \ln 2)2^{(C+D)/\tau} \quad (3)$$

where \bar{V} has been defined in the usual way as

$$\bar{V} = \int_0^\tau V(a)v(a)da / \int_0^\tau v(a)da,$$

and $v(a)$ is the frequency function of age.

Because ρ_d is considered to be the critical density that leads to the addition of envelope growth-zones, one would expect it to be independent of τ ; \bar{V} should thus vary with τ according to the exponential term. We have tested this prediction against the dimensions of *Escherichia coli* B/r strain H266 growing with a variety of doubling times (Table 1). Non-linear regression analysis to fit equation (3) to average cell volume gave excellent results ($P < 10^{-6}$ from a two-tailed F -test of explained variance). The value obtained for $C+D$ (78.7 ± 7.6 min) is so close to accepted values¹⁴ as to preclude the possibility that ρ_d is exponentially dependent on the growth rate to any great extent. It should be stressed that equation (3) has been derived without any assumptions concerning the dependence of β , R or d on τ . Furthermore, the proportionality of \bar{V} to $2^{(C+D)/\tau}$ found here may also hold true for other Gram-negative bacilliform bacteria. This follows from the similar dependence of the average mass of *Salmonella typhimurium*^{12,15} on $(C+D)/\tau$ and the independence¹⁶ of the average cell density ρ .

In addition to a maximum at $\tau-d$, cell density goes through a minimum during each cycle. This minimum precedes $\tau-d$ by a fixed fraction of τ , $2-1/\ln 2$ or about 56%, and will thus occur after, at or before cell division according as $d/\tau <, =$ or $> m-1+1/\ln 2$; in all cases, the ratio ρ_{min}/ρ_d is constant and equal to $\frac{1}{2}\ln 2 \approx 0.94$. (By comparison, ρ/ρ_d , which is also independent of τ , is $2(1/\ln 2)^2 \approx 0.96$.)

Evidence¹⁷ for just such a variation in ρ over the cell cycle has recently been reported for exponentially growing *E. coli* K12, with measured values of 0.95 for ρ_{min}/ρ_d and 0.97 for ρ/ρ_d ; ρ/ρ_{min} was precisely as predicted, 1.020. The occurrence of the maximal density at cell birth and division is consistent with a d of around 44 min; the least-squares estimate provided by the surface-area model (Rosenberger *et al.*, submitted for publication) is 49 ± 4 min. The location of the minimal density, near the middle of the cell cycle, is also as expected.

The time before division at which the rate of envelope synthesis doubles, d , will depend on R and β and the way they vary with τ . The radius of *E. coli* B/r H266 decreases with τ (Table 1): over 90% of the variance ($P < 10^{-6}$) in $R(\tau)$ can be accounted for by the expression $R(\tau) = R_\infty 2^{1/\tau}$, where $R_\infty = 0.185$ μm and $\gamma = 33.6$ min. In order to define the relationship of d to growth rate, it is thus only necessary to determine how β varies with τ . In the absence of definitive data, two simple relationships are considered¹⁰ (see also Rosenberger *et al.*, submitted for publication): no dependence between β and τ , and inverse proportionality. The former predicts d to be a weak function of τ ; the latter to be a constant, $C+D-\gamma$, about 45 min. In either case, and depending on the growth rate, d could coincide with either the initiation or the termination of chromosome replication. This may explain the general lack of agreement in the literature regarding the particular event in the cell cycle considered to be associated with the rate change in envelope synthesis^{1,5,6}.

The dimensions predicted by models postulating linear and exponential rates of envelope synthesis are very similar¹⁸. We would thus like to point out that exponential surface extension between discrete changes in the number of zones can also explain the experimental results, as follows. If the rate of surface growth from a zone increases in proportion to cell mass until the zone reaches its maximum capacity, as is the case in fungi⁷, then cell density will be constant except for the period when all existing zones are acting at full capacity and new ones have not yet become operative; provided this period is short compared to τ , \bar{V} will still be proportional to $2^{(C+D)/\tau}$.

While there seem to be no recognised molecular mechanisms through which changes in density are able to derepress enzyme synthesis, changes in solute concentrations can do so.

Table 1 Mean length \bar{L} and radius R of *E. coli* B/r at various doubling times τ

	24	3.29	0.466

E. coli B/r strain H266 was grown in minimal salts medium supplemented with the carbon source indicated¹⁰. Cells, fixed in OsO_4 and agar-filtered, were measured from projections of electron micrographs at a final magnification of 12,000.

If the limiting precursor of an envelope component were synthesised with the same kinetics as is mass, its concentration too would reach a maximum at $\tau - d$; for a relatively large flux and low average concentration, such an increase could be quite substantial.

One should perhaps consider another possibility: that cell radius varies during the cell cycle in such a way as to maintain p constant. Of course, if the cell wall were completely free to adjust to changes in hydrostatic pressure, R rather than p would reach a maximum at $\tau - d$. Here too, the maximum would be only 4% above the average value and 6% above the minimum—variations that are probably beyond experimental resolution¹³. But cell wall, once formed, is able to withstand considerable internal pressures and yields very little (if at all) to forces of expansion. Mitchell¹⁹ measured the phosphate-impermeable volume of stationary *E. coli* as a function of external NaCl concentration in conditions that were later found to cause a substantial cleavage of the peptides crosslinking murein chains²⁰. Nevertheless, less than half the increase in internal osmotic pressure was compensated for by a change in cell volume, the remainder being balanced by the hydrostatic pressure exerted by the cell wall²¹. In principle, in the case of growing cells, new cell wall could attain the necessary magnitude as it is being synthesised in order to maintain constant density despite the rigidity of formed wall. If we assume, as a conservative upper limit, that formed wall can adjust sufficiently to compensate for half the change in volume required to keep p constant, then one can show (and verify easily) that in order for new wall to compensate for the other half, the radius must increase exponentially along the length of the cell from a value of R_0 ($= 2M_0 \ln 2 / \beta p \tau$, where M_0 is the mass at birth) at the location corresponding to cell birth to a maximum of $2R_0 2^{-d/\tau}$ at doubling. There it drops abruptly to half its size and then resumes its exponential climb back to R_0 . Such behaviour is clearly at variance with observation, and we must reject the possibility of constant p and adjustable R .

The applicability of our model will depend in part on the extent to which it can explain the differences in shape observed in closely related strains of *E. coli* growing in a variety of conditions^{5,6,10,14,16,22}, including those produced by specific mutations^{5,23,24}. In this connection, the bizarre alterations of shape found in *E. coli* 15T⁻ growing rapidly in low thymine concentrations²⁵, may be of particular interest.

Suppression of fever at term of pregnancy

THE newborn human is often unable to develop a fever following exposure to various infectious agents^{1–3} and newborn lambs are similar, in that they do not develop a fever in response to a bacterial endotoxin challenge in the first few days of life⁴. Lack of the febrile response is thought to be due to the need for a process of 'sensitisation' of the lambs, or to the immaturity of some aspect of the fever-production process^{5,6}. Newborn guinea pigs and rabbits also, do not become febrile or show a diminished response to a challenge with endotoxin during early postnatal life^{7,8}. We have examined the response of the pregnant ewe to pyrogens at and near the time of birth, for although they become febrile during pregnancy⁹, their response to endotoxin at term has not been studied. We report here that the febrile response induced by a bacterial endotoxin or by endogenous pyrogen is suppressed in the ewe for a period extending from 2 to 5 d prepartum to several hours postpartum.

Suffolk, Dorset and cross-bred ewes were studied at various times ranging from 8 d prepartum to 60 h postpartum. The ewes were injected by way of the jugular vein with 30 μg of bacterial pyrogen derived from *Salmonella abortus equi* (SAEP) in a 3-ml volume of sterile physiological saline. This quantity of SAEP gave a fever of $1.3 \pm 0.15^\circ\text{C}$ in non-pregnant adult sheep. The SAEP was administered to each ewe at 3-d intervals, in order to avoid the production of refractoriness to the pyrogen. Temperatures were measured continuously by a thermistor probe inserted about

Fig. 1 The proportion of ewes not responding with a fever following 30 μ g SAE pyrogen given intravenously is represented by the vertical bars. The animals were injected from times ranging from 5 d prepartum to 60 h postpartum. The responses of non-pregnant adult ewes is represented on the far right. The broken vertical line represents the time of birth.

20 cm beyond the anal sphincter and the output of the thermistor was displayed on a recorder. Rectal temperature was monitored until it had remained steady for 30 min before injection and then was monitored for 200 min after injection. A fever was considered to be a 0.4 °C or greater rise in temperature above that at the time of injection.

Endogenous or leukocyte pyrogen (EP) was prepared from sheep granulocytes, obtained by a sterile peritonitis induced with 3% starch solutions after the method of Fessler *et al.*¹⁰ This EP was found to be endotoxin-free using Murphy's rabbit test¹¹ and by the Limulus assay for Gram-negative material^{12,13}. A fever with a maximum of 1.85 ± 0.10 °C was produced by 0.2 ml of this EP in the non-pregnant adult sheep. The EP was injected in the same manner as was the SAE after it was found that the ewes did not respond to SAE with a fever. This procedure was intended to determine at which step in the sequence of events of fever production the inhibition was manifest, since EP is thought to be released from cells of the reticuloendothelial system once they are stimulated by the endotoxin or antibody-endotoxin complex. It is thought that EP stimulates some higher centre(s) which react by driving heat production and heat conservation.

The ewes responded with fever to SAE until a time which varied between 4 and 2 d prepartum. As shown in Fig. 1, 5 d before parturition, all the three ewes tested developed a fever similar to that in the non-pregnant controls. At 3 and 4 d before parturition four of seven ewes were afebrile following the injection of pyrogen. At days 1 and 2 prepartum, eight of the nine ewes tested failed to develop a fever. The ewes were injected with SAE 5 h postpartum, and 11 of 17 remained afebrile, whereas at 32 h postpartum, 12 of 14 ewes could again become febrile. By 60 h, all the six ewes tested were febrile. Most EP challenges fell within the 0–48 h prepartum period, as they were given after the ewe became afebrile to SAE. Although the number of experiments using EP is small, it was observed that four of seven ewes, 1 and 2 d prepartum responded to EP with fevers whereas three were afebrile. It was not possible during this breeding season to do additional experiments with EP at other times. All control animals responded with fever following every injection of both SAE and EP.

These data suggest the presence of some naturally occurring fever-suppressing system. First, there could be a humoral antipyretic agent which is shared by the circulation of both ewe and foetus. This is compatible with the observation that the newborn lamb also does not become febrile to either SAE or EP. Second, it could be possible that the ewe is afebrile because of a circulating antipyretic but the newborn lamb, on the other hand, is afebrile as the result of some immature cellular system in the fever pathway. The fact that the EP never produced a fever in the newborn animal suggests that it may be afebrile by some other mechanism or, consistent with the first possibility, that the titre of antipyretic

substance is much higher than in the ewe. Injections of EP were given in order to determine at which step in the sequence of events inhibition is occurring within the system. The differential response to the EP among the prepartum ewes, four febrile and three afebrile, at 0–48 h before birth, suggests that the inhibition occurred after EP had been elaborated^{11–14}. An explanation consistent with this is that with our dose of EP, the titre was higher than that naturally produced by the reticuloendothelial system in response to 30 μ g SAE. Since EP produced a fever in four of seven animals, it is likely the inhibition was at some stage after the elaboration of EP and raises the possibility that higher doses of EP may overcome this inhibition. This explanation requires that inhibition is not total but that the putative antipyretic acts by competitive inhibition of EP or some later mediator of fever.

The evidence presented here that there is a suppression of fever near term, would indicate some adverse consequences of fever at term. The ewes which produced fevers to EP during their critical period, however, showed no more trouble with parturition than the afebrile mothers. The lambs of EP febrile mothers were no less viable than those of EP afebrile mothers, judging from observations such as ability to suckle soon after birth, strength and growth rate.

It remains to be seen if term ewes can become febrile to any pyrogenic agent other than EP or if any other mammals, particularly human, show in some way this endogenous antipyretic phenomenon. The identity of such an antipyretic is another critical question and its characterisation could add significantly to our understanding of the febrile process and antipyresis.

Action of *Corynebacterium ovis* exotoxin on endothelial cells of blood vessels

Corynebacterium ovis (*C. pseudotuberculosis*) causes suppurative infections of sheep, goats and horses and occasional infections in other species². Like *C. diphtheriae*, it produces a powerful exotoxin *in vitro*. But unlike the situation with *C. diphtheriae*, there is no evidence of acute or chronic intoxication, while the lesions are characteristically pyogenic with suppuration and abscess formation at the initial site of infection (usually a skin wound). This is followed frequently by secondary abscess formation in regional lymph nodes and sometimes internal organs. Toxin is produced *in vivo* as well as *in vitro* because circulating antitoxin is found in infected animals. The major role of *C. ovis*

toxin in natural infection seems to be facilitation of the spread of the causative bacteria by its action as a permeability factor. It thus causes marked leakage of plasma from small blood vessels at the site of infection which floods lymphatic spaces and increases the risk of bacteria being carried by lymphatic drainage from the site of infection to regional lymph nodes^{3,4}. We now report experimental evidence that *C. ovis* toxin is a phospholipase D which attacks the sphingomyelin of endothelial cells of blood vessels.

We considered two possible modes of action for *C. ovis* toxin. The first was an indirect effect in which toxin acts on mast cells closely associated with blood vessels, leading to liberation of histamine and 5-hydroxytryptamine which then act on adjacent endothelial lining membranes of blood vessels, increasing their permeability. The second was a direct action of the toxin molecule on endothelial cells. When mast cells from the peritoneal cavity of rats and mice were exposed to toxin, no degranulation was observed. This accorded with the observations of Smith and Miles⁵ who found no evidence of liberation of histamine or 5-hydroxytryptamine when *C. ovis* culture was introduced into the peritoneal cavity of the rat.

Souček *et al.*^{6,7} have reported that purified *C. ovis* toxin is a phospholipase D which splits sphingomyelin into *N*-acyl-sphingosyl (ceramide) phosphate and choline. This action occurred both when purified sphingomyelin was used as substrate and when the lipid was incorporated in the lipoprotein of the cell membrane of erythrocytes. This suggested that *C. ovis* toxin acts in a similar manner on the sphingomyelin of endothelial cells lining blood vessels. We have examined this by exposing living endothelial cells lining the aorta of sheep and rabbits to purified *C. ovis* toxin. We then examined chloroform:methanol extracts of the treated cells for evidence of ceramide phosphate and choline—the breakdown products of sphingomyelin by a phospholipase D. Washed sheep and rabbit erythrocytes were also exposed to toxin for comparison.

Toxin was precipitated from culture filtrates by 35–65% saturation with ammonium sulphate. This was followed by ion-exchange chromatography on a column of Sephadex CM 50, pressure dialysis and freeze drying. (Further purification has recently been achieved by use of DEAE columns, but the biological properties have remained essentially the same. Details will be published elsewhere.) A solution of 1 mg ml⁻¹ in phosphate-buffered saline (PBS) had a minimal reactive dose in the rabbit of 0.2 ml of 10⁻⁵ dilution. The aortae of five sheep and two rabbits were exposed to toxin (1 mg ml⁻¹ in phosphate-buffered saline containing 4 mM MgCl₂); and as controls, aortae of two sheep and one rabbit were similarly treated either with toxin inactivated by heating at 60 °C for 2 h, or buffer only. Animals were anaesthetised and most received heparin intravenously to prevent clotting. After bleeding out, the abdomen and thorax were quickly opened, cannulae were inserted into the aortic arch and near the bifurcation of the abdominal aorta; the aorta was then perfused with PBS while all arterial branches were ligated and severed. The aorta was removed, filled with toxin or control fluid, suspended in PBS and held at 37 °C for 1–2 h. Phospholipids of the endothelial lining were then extracted by chloroform:methanol (2:1 v/v) based on the method described by Dawson *et al.*⁸. Erythrocytes from 50 ml of heparinised blood were washed three times in PBS containing 4 mM MgCl₂. One-half of the deposited cells were mixed with toxin (1 mg ml⁻¹) and the other with heat-inactivated toxin. Suspensions were incubated at 37 °C, and cells were finally extracted with chloroform:methanol (2:1).

Equal volumes (200 µl for aortae, 150 µl for erythrocytes) of control and treated extracts were spotted on to thin-layer chromatography (TLC) plates (Merck silica gel 60F-254). Sphingomyelin and ceramide phosphate were included as markers. TLC plates were developed with chloroform-methanol-water-acetic acid (65:50:4:1 by volume). The phospholipids were detected by a phosphorus-specific spray⁹. Some TLC plates were sprayed with a choline-detecting reagent¹⁰.

In all extracts of toxin-treated aortae and erythrocytes of both

Fig. 1 TLC plate extracts of toxin-treated and control aortic endothelium and erythrocytes of sheep. Vertical lanes: a, sphingomyelin; b, control aortic extract; c, toxin-treated aortic extract; d, synthesised ceramide phosphate; e, toxin-treated erythrocytes extract; f, control erythrocytes extract. Horizontal lanes: BP, blood pigments; CP, ceramide phosphate; PE, phosphatidyl ethanolamine; PI, phosphatidylinositol; PS, phosphatidyl serine; S, sphingomyelin; O, origin.

sheep and rabbits, sphingomyelin was degraded to ceramide phosphate and choline. Figure 1 shows a TLC plate of the sheep extracts sprayed for phospholipids.

After completion of these experiments our attention was drawn to reports that certain enzymes, including phospholipases, may not be inactivated by chloroform:methanol used to extract tissues. If this were the case with *C. ovis* toxin, then the ceramide phosphate demonstrated in our extracts of aortic endothelial cells and erythrocytes may not have resulted from direct action of toxin on sphingomyelin bound to protein in the endothelial cell membrane, but may have occurred as the result of phospholipid degradation by still active toxin after extraction by organic solvent. We therefore set up the following tests. (1) We mixed 0.5 ml of emulsion of sphingomyelin in water with 0.5 ml of toxin (1 mg ml⁻¹ in phosphate-buffered saline + MgCl₂); added 20 ml of chloroform:methanol (2:1 v/v), incubated them together for 2 h at 37 °C and ran the mixture on TLC plate. (2) As for (1) but the mixture was tested on a TLC plate immediately after mixing. (3) and (4) as for (1) and (2) but a suspension of washed sheep erythrocytes was substituted for sphingomyelin emulsion. In each case phospholipase D activity of *C. ovis* toxin was annulled by exposure to the chloroform:methanol, even for a few minutes.

We have thus confirmed (the evidence of Souček *et al.*^{6,7}) that *C. ovis* toxin is a sphingomyelinase which splits the sphingomyelin of the cell membrane of erythrocytes into ceramide phosphate and choline, but we have extended our experimental observations to show that the toxin has a similar action on the sphingomyelin of the vascular endothelial membrane. This raises the question of the possible significance of this enzyme action of *C. ovis* toxin in relation to its permeability effect on blood vessels.

It is interesting that *C. ovis* toxin produces its permeability changes rapidly within minutes. This seems to exclude the possibility that this early action was due to permeability factors derived from leukocytes or platelets which are not seen to adhere to the luminal surface of endothelial cells until 30 min or longer after injection of toxin.

In spite of extensive study, little is known of the biochemical and biophysical causes of increased vascular permeability which is such a striking feature of acute inflammation and the action of certain bacterial toxins^{11–14}.

Majno *et al.*^{15,16} have shown that exposure of small blood vessels to the well-known permeability agents, histamine and 5-hydroxytryptamine, leads to partial disconnection between

endothelial cells along intercellular junctions, thus forming gaps through which leakage of plasma occurs. Among possible factors leading to the formation of such gaps may be the chemical breakdown of specific junction constituents (for example, the protein connexin isolated by Goodenough¹⁷ from junctions between mouse liver cells), and/or increased tension on junctions resulting from contraction of the cell membrane caused by chemical changes in important constituents over the whole cell surface. Sphingomyelin, which is broken down by *C. ovis*, forms part of an important structural lipoprotein of the cell membrane. It is interesting that the alpha toxin of *Clostridium welchii*, another active permeability agent, is a phospholipase C and attacks lecithin, the phospholipid component of another important structural lipoprotein of cell membranes¹⁸.

We are examining the possible significance of the enzyme action of *C. ovis* toxin on sphingomyelin in relation to its permeability effect on blood vessels.

We thank Dr R. M. C. Dawson for advice; Dr D. E. Bowyer, P. E. Davies and M. A. Reidy for helpful discussions; Mr G. A. Embleton and Dr R. M. Moor for anaesthesia and facilities; Mr C. R. Farrell and Mrs J. P. King for technical assistance, and Mr P. C. Curtis for photography. We also thank Professors R. I. N. Greaves and P. Wildy for hospitality and facilities in the Department of Pathology, University of Cambridge. This work was supported by a grant from the Wellcome Trust.

Differential cell adhesion may result from nonspecific interactions between cell surface glycoproteins

I SUGGEST that if different cell types have different glycoprotein coatings they will tend to adhere to each other with different intensities, and sort out into separate tissues simply as a result of weak nonspecific interactions between the glycoproteins without any special mechanisms such as binding by specific recognition proteins. This could be responsible for many, but certainly not all, cell recognition and adhesion phenomena (reviewed in refs 1 and 2).

Cells are coated with glycoprotein and glycolipid so they would seem from the outside like giant macromolecules of glycoprotein (for simplicity, the glycolipid can be pictured as providing extra oligosaccharide chains in this glycoprotein) and they ought to show behaviour analogous to the behaviour of large polymers in solution.

Large polymers when mixed in solution tend to undergo incompatible phase separation, the solution separating into immiscible phases each containing predominantly one polymer

species³. For example, a sufficiently concentrated solution of polyethylene glycol and dextran separates into two phases, and many other polymers, when added to the system, will form further separate phases. Two separate phases can even form from solutions of one polymer and a small molecule, for example polypropylene glycol and potassium phosphate or glucose³. The behaviour of small molecules in solution is usually determined mainly by the entropy of dilution, representing random distribution of the solute throughout the solvent. For polymers the entropy of dilution remains, to a first approximation, the same per molecule but the enthalpy of interactions between the polymer molecules increases in proportion to the size of the molecules and at sufficiently high molecular weight may become the dominant influence. For hydrophilic polymers these interactions will mainly be weak and non-specific, such as hydrogen-bonding, van der Waal's, fixed dipole-dipole and hydrophobic interactions. Such interactions are generally stronger between like molecules than between unlike molecules, so large polymers tend to segregate into separate phases⁴. (There are, of course, many polymers, particularly charged ones, that do interact with each other more strongly than with themselves. They may form complexes that separate as a single phase from solution leaving a polymer-free phase.) An additional factor promoting segregation of unlike molecules arises from steric effects. Each polymer molecule excludes other molecules from a volume of solution often much larger than its physical volume, particularly if it is extended rather than globular⁴. At sufficiently high concentration the freedom of polymer molecules to pack together, represented by an entropy term, becomes a significant factor favouring the segregation of polymer species of different molecular size. (For further discussion and thermodynamic treatment see refs 4 and 5.) So mixed solutions of hydrophilic polymers tend to show phase separation, and the larger the molecules the greater the tendency and the weaker the interactions needed to cause phase separation. It has already been pointed out that proteoglycans and glycoproteins ought to show this behaviour⁶.

If cells of different types have different glycoprotein coats they would in general be expected to form separate phases, that is, to sort out into aggregates of a single type of cell. If they are suspended in a medium such as plasma, containing small polymers, or even just saline, one phase might be cell-free, in other words cells of all types would aggregate, then sort out within the aggregate. (This, incidentally, may have something to do with the need for serum components in culture media for cells⁷.) It is well known that phase separation is a good description of the sorting out of embryonic cells. To quote Moyer and Steinberg⁸ "rearrangements [of cell aggregates] . . . resemble in striking detail the rearrangements of immiscible liquids", cells corresponding to molecules of the liquids.

The energy released by phase separation compares favourably with the energy needed to bind two cells together. Agglutination of two red cells requires less than 10^2 antibody molecules⁹ which would give about 10^3 kcal of binding energy per mol of cells. When, for example, two like cells come into contact over an area of $50 \mu\text{m}^2$, there is a loss of $100 \mu\text{m}^2$ of interface between the cells and either medium or unlike cells. For these cells to adhere as strongly as the red cells the interfacial free energy released by the contact would have to be only 10^3 kcal per $6 \times 10^{23} \times 100 \mu\text{m}^2$ or 7×10^{-5} erg cm^{-2} , much less than the 10^{-3} to 10^{-1} erg cm^{-2} typical of the examples of phase separation above³. It corresponds to only 2×10^{-3} kcal per mol of surface glycoprotein if the cell surfaces have the same surface density of integral membrane glycoproteins as the red cell¹⁰, 10^6 per $100 \mu\text{m}^2$.

So merely by carrying different glycoprotein coats cells might well be expected to show differential adhesion phenomena. For example, in development different cell types would form separate phases, that is, tissues. Less obvious examples could be the binding of desialylated serum glycoproteins to liver cell surfaces, though this may be mediated by a true lectin activity¹¹,

and the selective penetration of capillary walls by leucocytes, where the capillary wall can be viewed as a phase into which leucocytes can reversibly partition, but which is immiscible with other components of blood.

This explanation of apparently specific cell interactions in terms of large numbers of weak nonspecific forces conflicts particularly with the widely held view that cells interact through specific binding by recognition proteins with lock-and-key active sites^{1,2,11}. Such proteins probably do play a part in some mechanisms^{1,2,11}; the point is that they may not be necessary. Several authors¹ have previously suggested that the forces between cells are nonspecific; in particular, Steinberg¹² showed some years ago that nonspecific forces could produce immiscibility of aggregates of different types of cell. One way in which the consequences of the view presented here may differ from the consequences of the lock-and-key view is that immiscibility of dissimilar glycoprotein coats on different cell types can provide a repulsive interaction in the sense that active cell migration through an incompatible phase would be resisted. In contrast the simple lock-and-key picture tends to predict positive or zero adhesion.

Hybrid cell lines secreting monoclonal antibody specific for major histocompatibility antigens of the mouse

HYBRIDISATION of a myeloma cell line with hyperimmunised spleen cells can provide hybrid cell lines secreting monoclonal antibodies of predefined specificity^{1,2}. Lines have thus been established which secrete homogeneous antibodies against antigens such as sheep red blood cells¹, the hapten 2,4,6-trinitrophenyl², influenza virus³, horse red blood cells, the haptens (4-hydroxy-3-nitrophenyl)acetyl and (4-hydroxy-5-iodo-3-nitrophenyl)acetyl, group A streptococcal carbohydrate, hen egg lysozyme, chicken γ globulin, the synthetic polypeptide poly-L-(Tyr, Glu)-poly-D,L-Ala-poly-L-Lys⁴ and antigens encoded by the major histocompatibility complex (MHC) of the rat⁵. We report here the derivation of three cloned hybrid cell lines which synthesise antibodies detecting different public antigenic specificities of the mouse H-2 complex. These hybrid cell lines can be grown in the mouse as ascites tumours, and the ascites fluids obtained contain large quantities of homogeneous anti-H-2 antibodies.

BALB/c (H-2^d) spleen cells hyperimmunised with CBA (H-2^k) lymphocytes were fused with the mouse myeloma P3-X63-Ag8 using polyethylene glycol as a fusion reagent (see

Fig. 1 legend). Culture supernatants of 200 individual hybrid cell lines obtained in one fusion experiment were screened for anti-H-2 activity by a complement dependent cytotoxicity assay or a cellular radioimmunoassay in which antibody bound to target cells was monitored by uptake of ¹²⁵I-labelled staphylococcal protein A (¹²⁵I-SpA)⁷. Five of the 200 supernates were cytotoxic to CBA but not BALB/c target cells. Their protein A assay response indicated that the secreted antibodies belonged to the IgG class⁸ (Fig. 1). No hybrid cell line was active in only one assay.

The hybrid cell lines were cloned in soft agar and three individual clones, one of each hybrid, with activity against CBA target spleen cells, were selected for further characterisation of their products. These clones, 5R4, 27R9 and 30R3, were injected intraperitoneally into Pristan-pretreated BALB/c mice. The hybrid cell antibodies were purified from ascites fluid by agarose block electrophoresis. Spectrophotometric determination of the protein concentration in different fractions revealed a single peak in the γ globulin region close to the starting point. The amount of purified protein in this peak was calculated from the optical density at 280 nm, assuming an extinction coefficient E (1 cm pathlength) of 1.4 for a solution containing 1 mg protein per ml. The yields were 40 mg from 4 ml ascites fluid for antibody 5R4, 45 mg from 3 ml ascites fluid for antibody 27R9, and 45 mg from 3 ml ascites fluid for antibody 30R3. Microzone electrophoresis and isoelectric focussing demonstrated that the protein peak contained both the P3-X63-Ag8 myeloma protein MOPC 21 (γ 1, κ) (refs 1, 12) and additional protein components, presumably representing the cytotoxic antibody and hybrid molecules¹². Most of the antibody activity was found in the fractions with the highest protein content. These were analysed in the Ouchterlony

Fig. 1 BALB/c (H-2^d) mice were primed by skin grafting against CBA (H-2^k) allo-antigens and hyperimmunised by three intraperitoneal injections of $1-3 \times 10^7$ CBA spleen cells in 10-d intervals beginning with the first injection 2 weeks after priming. Five days after the last injection, cells from four BALB/c spleens were fused with the myeloma P3-X63-Ag8. Cells were fused employing a modification¹⁴ of the method described by Pontecorvo *et al.*¹⁵, except that polyethylene glycol with a molecular weight of 4,000 was employed and the ratio of spleen to myeloma cells was 2:1. After fusion, the cells were distributed in multiwell tissue culture plates (Costar No. 3524) at a density of 2×10^6 spleen cells per well and cultured in HAT medium¹. Two weeks later, cell growth became microscopically evident in 200 out of 240 wells. Culture supernatants of these positive wells were assayed for anti-H-2 activity either by a two step microcytotoxicity assay using rabbit serum as a source of complement (a gift from Dr J. Jensenius, Copenhagen) or by a cellular radioimmuno assay in which antibody bound to target cells is monitored by subsequent uptake of ¹²⁵I-labelled staphylococcal protein A which binds exclusively to immunoglobulin of the IgG class⁸. We followed the method described by Dorval *et al.*⁷. The titration curves for (a) cytotoxicity and (b) ¹²⁵I-binding properties of culture supernatants of hybrid cell lines 5 (●), 27 (○) and 30 (▲) are shown. Five out of 200 hybrid cell lines in this particular fusion experiment secreted anti-H-2 antibodies. One of the five hybrids lost its activity and another was lost by bacterial infection. In other fusion experiments, more than 1,000 hybrid cell lines were screened for anti-H-2 activity, but no positive lines were detected. At present we cannot define the precise experimental conditions to reproduce the successful hybridisation.

technique using class and subclass specific antisera (obtained from B. Liesegang & A. Radbruch, Cologne, and Meloy Co.). None of the three hybrid antibodies reacted with anti-μ and anti-α antisera. In all cases, precipitin lines appeared with anti-γ1 antisera, while antibody 30R3 reacted with anti-γ2b, and antibodies 5R4 and 27R9 with anti-γ2a. No reaction was found with anti-λ sera. This suggested that all preparations contain MOPC 21 chains as already indicated by microzone electrophoresis and isoelectric focussing, and that antibody 30R3 carries γ2b and antibodies 5R4 and 27R9 γ2a heavy chains. All three antibodies probably possess κ light chains.

Ascites fluids containing antibodies 5R4, 27R9 or 30R3 were tested on different H-2 haplotypes and intra-H-2 recombinant haplotypes to determine the antigenic specificities detected by these monoclonal antibodies (Table 1). The antibodies secreted by the three clones exhibited strong reactivity on CBA (H-2^k) but did not react with BALB/c (H-2^d) or DBA/2J (H-2^d) spleen cells. To determine whether H-2 specificities are detected by the antibodies, they were tested on B10.BR (H-2^k) and B10.D2 (H-2^d) target cells, which share the B10 background and differ only in their H-2 haplotypes. All three antibodies reacted with B10.BR (H-2^k) but not with B10.D2 (H-2^d), and thus can detect specificities of the H-2^k haplotype.

Various intra-H-2 recombinant strains were used to evaluate detection of the specificities of the K, I and D regions of the H-2 complex. All three antibodies reacted strongly with B10.A (H-2^a) target cells which have the K end of H-2^k and the D end of H-2^d. Antibody 5R4 did not react with C3H.OH (H-2^{o2}) cells which carry H-2^k antigens of the D region, while antibodies 27R9 and 30R3 occasionally showed weak reactions with these cells at high concentrations. Antibodies 5R4 and 27R9 did not react with the intra-H-2 recombinant A.TL (H-2^{tl}) or with A.SW (H-2^s), while antibody 30R3 showed reactivity with both strains. This indicates that antibodies 5R4 and 27R9 do not detect Ia antigens of the H-2^k haplotype and that the corresponding antigens are also not present in the K region of the H-2^s haplotype. It further suggests that antibody 30R3 also does not react with Ia antigens but crossreacts with a specificity of the K region of H-2^s. Another strong argument against the detection of Ia determinants by these antibodies is

Fig. 2 Cytotoxic activity of antibody 30R3 on spleen target cells of different H-2 haplotypes. Ascites fluid of tumour-bearing BALB/c mice was used as the source of antibody 30R3. As the data were obtained in different assays, the cytotoxicity values are presented as cytotoxic indices (see legend to Table 1).

the fact that they kill close to 100% of spleen cells. This has not been observed with anti-Ia antisera since Ia antigens are predominantly expressed on B lymphocytes⁹. These data therefore suggest that all three antibodies detect determinants encoded by the K region of the H-2 complex.

Further experiments demonstrated that antibodies 5R4 and 27R9 showed no reactivity on C57BL/6 (H-2^b), while antibody 30R3 showed 100 to 1,000-fold lower cytotoxic activity than on CBA (H-2^k) or B10.BR (H-2^k) cells. All three antibodies reacted with antigenic specificities also present on B10.R.III cells which carry the H-2^r haplotype. Antibodies 5R4 and 30R3 but not 27R9 also displayed activity on SWR/J (H-2^s) cells. Comparison of these results with the distribution of antigenic specificities of the K region of the H-2 chart⁶ suggests that antibody 5R4 may detect specificity H-2.11, antibody 27R9 specificity H-2.25 and antibody 30R3 H-2.5. This was confirmed (Table 1) when all three antibodies were entirely negative when tested on A.CA (H-2^f) cells, a haplotype which expresses none of the H-2 specificities, 5, 11 and 25.

The differences in reactivities of antibodies 5R4 and 27R9 observed on target cells carrying different haplotypes may be due to experimental variations and do not necessarily reveal a polymorphism of the corresponding antigenic determinants. Antibody 30R3, however, reacted equally strongly with H-2^k and H-2^s cells, showed weak crossreactivity with haplotypes H-2^r and H-2^a and very weak reactions with H-2^{o2} target cells (Fig. 2). However, all these haplotypes express specificity H-2.5 encoded either by the K region (H-2^{b,k,s,r,q}) or by the D region (H-2^{o2}) of H-2 (ref. 6). It has already been suggested by conventional H-2 serology that specificity H-2.5 encoded by different H-2 haplotypes reflects non-identical but crossreactive antigenic determinants^{6,10,11}. Assuming that antibody 30R3 really detects specificity H-2.5, the titre differences observed in the reactions of this antibody with target cells from different haplotypes (Table 1, Fig. 2) seem larger than titre differences with conventional anti-H-2 antisera, which have relatively low titres. This may be due to the different strain combinations used for raising conventional antisera⁶ and for the production of antibody 30R3. In addition, even if the same strain combination had been used for the production of the hybrid cell antibody, one might still expect the fine specificity of this monoclonal antibody to be different from that of a complex antiserum. It is indeed striking to see that the antigenic specificities detected by our three hybrid cell antibodies correlate largely with antigenic specificities enlisted in the H-2 chart⁶. The exquisite specificity of serological typing reaction thus seems to be fully retained at the level of monoclonal antibodies. This finding is important¹³, and suggests that monoclonal antibodies will play a key role in future histocompatibility typing.

We thank Dr C Milstein for the gift of the myeloma P3-

Cytotoxic T cells learn specificity for self H-2 during differentiation in the thymus

CELL mediated immune reactions in mice involving cytotoxic thymus derived lymphocytes have two important features; they are antigen-specific¹ and the structures coded for by the major murine histocompatibility gene complex (H-2) play an important part in killer cell-target cell interaction¹. This finding is not unique to mice since it has also been reported for rats, humans and chickens²⁻⁴. Two hypotheses have been suggested to explain this dual specificity of T killer cells; one proposes that T killer cells possess two separate structures, one of which recognises self H-2 structures and the other a non-H-2 antigen (dual recognition). The other hypothesis proposes that T killer cells possess one receptor which recognises an H-2 antigen modified by a non-H-2 antigen (modified self)^{1,5}. Evidence to test these hypotheses was sought by preparing chimaeras made by reconstituting lethally irradiated F₁ mice with bone marrow stem cells of one parent (Parent→F) refs 6-8 or neonatally tolerant mice⁹ (mice of a parental H-2 type injected with F₁ cells as neonates). As a result, Parent → F₁ chimaeric lymphocytes lysed

infected and trinitrophenyl (TNP)-modified targets of both parental H-2 types, suggesting that H-2 antigens of the killer cells were not involved in the lytic interaction. In contrast, lymphocytes from neonatally tolerant mice did not lyse infected targets from the incompatible parent⁹. Although these results can be explained by postulating a single receptor, they also fit the dual recognition hypothesis⁶⁻¹⁰. Bevan has shown that irradiated bone marrow chimaeras of the type (A × B)F₁ → Parental A recipient generated preferentially cytotoxic T cells against minor histocompatibility antigens in association with the H-2 haplotype of the recipient A; he concluded that the chimaeric host determines the specificity of T cell restriction either through a thymic selection process as proposed by Jerne or alternatively through an antigen presentation mechanism.

In similar experiments with F₁ → Parent chimaeras, we found that tolerance alone was again not sufficient to generate both virus-specific and TNP-specific cytotoxic T cells against antigen in association with the tolerated H-2. These results and studies on the role of the thymus in the differentiation of H-2 restricted killer cells seem to indicate that precursor T cells from lymphohaemopoietic stem cells are selected to recognise the H-2 markers during their differentiation in the thymus; this learning process is independent of the T cell's own H-2 haplotype¹⁶.

F₁ hybrid → Parent chimaeras were formed by irradiating parental mice with 925-950 rad and then reconstituting them with F₁ bone marrow cells⁷. The chimaeras were infected 10-12 weeks later with vaccinia virus [10⁷ plaque forming units (PFU) per recipient] and killed 6 d later. Spleen cells from each individual were typed serologically for H-2, after which virus-specific cytotoxicity was assessed in a ⁵¹Cr release assay on infected and uninfected target cells (Table 1). Spleen cells from other F₁ → Parent chimaeras were also typed for H-2 and then sensitised *in vitro* against TNP-modified stimulator cells (Table 2). The serological results show that the lymphocytes of the F₁ → Parent chimaeras were all of F₁ type. However, cytotoxic activity was directed exclusively against infected or TNP-modified targets of the recipient parental type but not against normal targets of both parental H-2 types either *in vitro* or *in vivo*. Thus, cytotoxicity was found only against targets that were H-2 identical with F₁ donor and parental chimaera recipient, but not against targets of the second parental H-2 type, despite the inherent tolerance of F₁ lymphocytes for both parental antigens and the presence of large amounts of infected or TNP modified cells expressing all relevant H-2 antigens. Other chimaeras were constructed of the type (A × B)F₁ → (A × C)F₁. When lymphocytes from such chimaeras were tested in the TNP system and sensitised against TNP (B × C)F₁ cells, strong TNP-specific cytotoxicity was generated against C-TNP but none against B-

* Recipient mice were irradiated with 925 rads and reconstituted with 2 × 10⁷ twice anti-θ plus C treated bone marrow cells. Chimaeras were infected 10 weeks later with about 10⁷ plaque forming units of vaccinia virus WR⁷. Their spleen cells were typed for H-2; for both chimaeras > 95% of the lymphocytes were lysed by anti-K^b and anti-K^d antiserum. Virus specific cytotoxic T cells were tested for 6 h on infected or uninfected target cells⁹. The spontaneous release from L cells was about 25%, from D2.GD macrophages about 45%.

† The results are given as means of triplicate determinations that were corrected for spontaneous release; water released about 80% of the incorporated ⁵¹Cr and this was taken as 100% release; s.e.m. were smaller than 5%.

‡ Significantly different from relevant controls (P < 0.01).

*Chimaeras were prepared and typed for H-2 as in Table 1. Spleen cells (10^7 ml^{-1}) were cultured for 5 d with trinitrobenzene sulfonate (TNBS) coupled stimulator spleen cells ($5 \times 10^5 \text{ ml}^{-1}$) irradiated with 1,000 rad as described previously¹².

†Spleen cells were (10^6 ml^{-1}) cultured for 3 d in the presence of $10 \mu\text{g ml}^{-1}$ bacterial lipopolysaccharide, collected and coupled with TNBS and labelled with Cr^{51} (ref. 12). The attacker to target cell ratio was 50:1.

‡Values are means of duplicates corrected for spontaneous release. The 100% release was determined by freezing and thawing the cells 3 times. s.e.m. values were smaller than 5%. The 4-h time point is given.

TNP (Table 2). This indicates that stem cells differentiate in the irradiated recipient to acquire H-2 (C)-restricted specificity that is host-dependent but independent of the H-2 type which the lymphocytes express themselves. The results from neonatally tolerant mice can be similarly explained⁹.

These results are compatible with the general idea of 'adaptive differentiation'¹⁰ and agree with similar data of Bevan¹¹, apparently implying that the H-2 type of the host in which T lymphocytes differentiate governs the specificity of subsequent H-2 restriction. One would therefore not expect parental strain cells depleted of alloreactivity to lyse antigen-modified fully allogeneic cells. Schmitt-Verhulst and Shearer¹³ showed that

lymphocytes of A origin which were deprived of anti B-alloreactivity by bromodeoxyuridine (BUdR) and light could not be sensitised specifically against B-TNP. However, their data and ours disagree with those of Wilson *et al.*¹⁴, who found that lymphocytes of A origin that were deprived of anti-B-alloreactive cells by filtration through irradiated F_1 animals could be sensitised specifically against B-TNP. This discrepancy cannot yet be resolved, but the different reactivities may have arisen from incomplete tolerance of the filtered lymphocytes or differences in the method of TNP modification.

Our results indicate that the chimaeric host determines the H-2 restricted specificity of cytotoxic T cells; they illustrate clearly

Table 3 Virus specific cytotoxic T cell activity generated in adult thymectomised irradiated C57BL/6 mice that were reconstituted with anti- θ treated F_1 bone marrow cells and transplanted with irradiated F_1 thymus of BALB/c \times C57BL/6 origin.

Recipient mice were thymectomised, 1 week later irradiated (950 rads) and reconstituted with twice anti- θ plus C treated bone marrow cells of F_1 origin; irradiated (900 rads) thymus lobes from 6-8-week-old F_1 donors were transplanted under the kidney capsule. These thymus chimaeras were infected about 3 months after reconstitution. 6 d later the animals were killed, the spleen cells typed for H-2 ($> 95\%$ were positive for H-2^b and H-2^d) and tested for cytotoxic activity in a 16-h test. Absence of the thymus of the host and presence or absence of thymic tissue under the kidney capsule were controlled histologically.

*Means of triplicate determinations; values are corrected for spontaneous release (MC57G: 26%, D2: 40%) and water release was taken as 100%.

†Significantly different from controls ($P < 0.05$).

that peripheral tolerance to H-2 is not sufficient to allow recognition by T cells of this same H-2 together with antigen. Thymus transplantation experiments indicate that it is the H-2 type of the thymus epithelial cells which determines the H-2 antigens treated as self by H-2 restricted T cells (Table 3). Adult thymectomised, irradiated C57BL/6 mice were reconstituted with bone marrow of BALB/c \times C57BL/6 origin and transplanted with two irradiated thymus lobes of BALB/c \times C57BL/6 origin under one kidney capsule. When infected with vaccinia virus 3 months later, cytotoxicity was generated for both parental H-2 type infected targets. This is in contrast with the results from $F_1 \rightarrow$ Parent irradiation bone marrow chimaeras, where activity was formed for the compatible recipient parental H-2 type only.

These two models differ with respect to the thymus of the two chimaeras and we may therefore conclude that the radioresistant part of the thymus, probably the H-2 specificity of the thymic epithelium, determines what differentiating T cells learn to recognise as self-H-2. Since thymectomy was histologically complete, and since virus-specific cytotoxic activity was generated for both infected H-2^b and H-2^d targets, and not for H-2^b alone, it follows that the transplanted thymus induced T cell maturation. The anti- θ plus C treatment was complete in depleting T cells, otherwise one would have expected that mature contaminating F_1 T cells would have given rise to a significant level of cytotoxicity in the second chimaera from the same group of animals, where no histological or functional thymus reconstitution was achieved. Therefore, it seems that precursor T cells learn to recognise as self the H-2 antigens expressed by the radioinsensitive portion of the donor thymus, that is, thymus epithelium. This capacity for self recognition differentiates independently from the H-2 haplotype of precursor T cells and independently from recognition of non-H-2 antigens.

Can these results best be explained by the single or dual recognition model? Lymphocytes from F_1 (A \times B) \rightarrow P(A) chimaeras generate antigen-specific killer T cells against H-2-compatible targets of parent A only, despite the fact that they were exposed to antigen in association with both A and B parental H-2 antigens. This could be explained by Jerne's speculation¹⁵ that T cells of a mouse A evolve from proliferating and mutating T cells that were specific for A to express specificity for 'different from A'. Within such a concept the one receptor hypothesis, which suggests that H-2 restriction results from an association of non-H-2 antigen at the level of induction could explain this experimental finding only if the rule were made that the specificity spectrum for modified self generated in thymus A cannot overlap with that generated in thymus B. This rule is unpredicted and unlikely, but cannot be excluded.

Because there is no precedent for the H-2 haplotype of the thymus restricting T cell-specificity (except perhaps for *Ir* gene effects), the explanation that T cells have independent receptor sites for thymus epithelial H-2 and for non-self antigen, and operate through dual recognition may be the more attractive one. Whether the two recognition structures are on one or two membrane molecules is not clear. These results and the concept that self-specificity is selected for in the thymus have important theoretical and practical implications for further experimentation. They may also provide an improved rationale for clinical attempts at reconstitution of immunodeficiency in humans. If the presented results are correct and apply to humans, it is predicted that (except for pure thymus hormone deficits) reconstitution of immunodeficient patients with completely HLA incompatible thymus epithelium or lymphohaemopoietic stem cells may result in differentiation of mature T cells that cannot interact with other T cells or B cells because they were taught in the thymus to recognise HLA structures as self that are not of their own HLA type. Therefore, functional immunological reconstitution of thymus and/or stem cell deficient patients with immunoincompetent thymus tissue or liver cells, for example, of foetal origin (to avoid graft versus host reactions), may depend on recipient and donor sharing at least one HLA-A or B and D haplotype.

We thank Drs D. H. Katz and B. S. Skidmore for anti- θ serum, Alana Althage and Sue Cooper for technical assistance and

Cell surface changes in alloantigen activated T lymphocytes

MANY interactions which take place between T lymphocytes and other cells are presumably mediated at the level of the cell surface. In a mixed leukocyte culture (MLC), interaction between allogeneic lymphocytes results in transformation of the responding small T lymphocytes to large blast-like cells and their development into killer, helper¹ and suppressor lymphocytes². Some blasts subsequently revert to small memory or 'secondary-type' lymphocytes³. An important question is whether significant changes occur in T lymphocyte membrane proteins as a result of these interactions. We have attempted to answer this question by comparing iodine-labelled surface proteins of the following cells: T lymphocytes before stimulation, blast cells and small lymphocytes purified by Ig velocity sedimentation from an MLC on day five, and reversion T lymphocytes following an additional 5 d of culture of the separated blast T lymphocytes. The results demonstrate that iodine-labelled components change during blast transformation and provide evidence for membrane differences between 'secondary-type' T lymphocytes and unsensitised cells.

Figure 1 shows radioactivity profiles resulting from co-electrophoresis of NP-40 extracts of ¹²⁵I-labelled murine thymus and spleen and ¹³¹I-labelled nylon column purified spleen T cells on a 5% acrylamide, 0.1% sodium dodecyl sulphate (SDS) gel. When analysed on these 5% gels, both spleen and nylon column purified T cells, Fig. 1b show three distinct peaks of radiolabelled proteins which have molecular weights of approximately 200,000 (200K), 187K, and 170K. (Preliminary SDS gel studies of plasma membrane preparations (G. Sundharadas, to be published) from ¹²⁵I-labelled cells also show three peaks in the 170K to 200K molecular weight

range). The presence of these peaks in the thymus preparation (Fig. 1a) and in nylon wool purified cells and the absence of any of the three peaks in macrophage or nude mouse spleen cell preparations (data not shown), are consistent with these being specific T cell-associated peaks. Trowbridge *et al.*⁴, using a 7.5–15% gradient gel, have reported the presence of a T cell-specific protein of molecular weight 200K in preparations similar to ours. The peak of molecular weight 240K in Fig. 1b

Fig. 1 NP-40 extracts of ^{125}I -labelled murine spleen and thymus and ^{131}I -labelled nylon column purified cells electrophoresed on SDS-polyacrylamide gels. Single cell suspensions were prepared by aseptically removing the spleen or thymus, and teasing them through a wire mesh into EHAA media. Aggregates were allowed to settle, the cells aspirated off and washed once in media. Erythrocytes were removed from the spleen cell suspensions by lysing with 0.15M NH_4Cl , 0.01M Tris Cl, pH 7.2. Nylon column purified T cells were prepared from spleen cell suspensions by passage over a nylon wool column according to Julius *et al.*⁷. Cells were washed three times in PBS, then $2\text{--}4 \times 10^7$ cells in 0.5 ml were iodinated with 1 mCi ^{125}I or ^{131}I (total concentration of iodide was $1 \times 10^{-6}\text{M}$) using the galactose-oxidase lactoperoxidase technique of Schenkein *et al.*⁸. Cell viability was determined before and after iodination; cell recovery was $>95\%$ and $>90\%$ of the cells were viable (by eosin staining) before and after iodination. After iodination, cells were washed three times with PBS, and lysed by addition of Nonidet P40 (Shell) to a final concentration of 0.2%. Nuclei were removed by centrifugation at 1,000g for 10 min. The supernatants were made 3% in SDS, 0.1M in β -mercaptoethanol, heated to 90°C for 3 min, and indicated samples co-electrophoresed on 6 mm \times 110 mm, 5% acrylamide 13% bi-sacrylamide gels containing 0.1% SDS, according to Laemmli⁹. Electrophoresis was stopped when the tracking dye reached the lower edge of the gel, and the gels separated into 1 mm fractions using a Gilson gel fractionator model B-200 GMA-GCB. Scintillator fluid (3a70B, Research Products International, Incorp.) 3 ml, was added to each fraction and the fractions counted in a Packard tricar liquid scintillation spectrometer model 3330 using window settings of 50–1,000 (^{125}I), 200–1,000 (^{131}I) and a gain of 50% (^{125}I) or 6% (^{131}I). The net counts of ^{125}I were corrected for overlap of ^{131}I counts into the ^{125}I -channel. Approximate molecular weights of the peaks were calculated from their position relative to those of known standards. *a*, Extracts of ^{125}I -labelled thymus cells (\bullet) and ^{131}I -nylon wool cell extracts (Δ). *b*, Extracts of ^{125}I -labelled spleen cells (\bullet) and ^{131}I -nylon wool cell extracts (Δ).

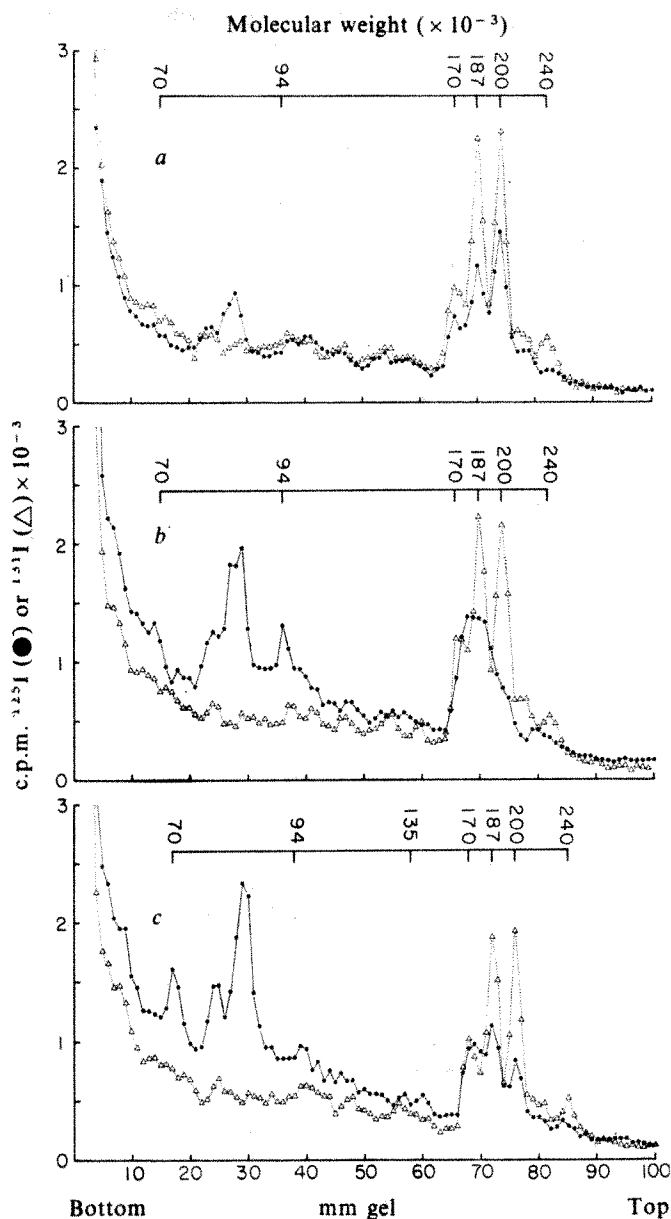

Fig. 2 NP-40 extracts of ^{125}I -labelled small lymphocytes, blasts, reverted cells and ^{131}I -nylon wool purified T cells, electrophoresed on SDS-polyacrylamide gels. Mixed leukocyte cultures were set up in 250 ml Falcon tissue culture flasks (50–75 ml media per flask), using culture conditions according to Peck and Bach¹⁰. Nylon wool purified T cells from B10.M mice were prepared as described in Fig. 1, and stimulated with allogeneic (B10.G) γ -irradiated (2,000R) spleen cells, using 2.5×10^6 responding and stimulating cells per ml. After 5 d in culture, cells were harvested, washed with PBS and separated into large, rapidly sedimenting 'blast' cells and small, slowly sedimenting lymphocytes on a 5–30% horse serum gradient by unit gravity velocity sedimentation¹¹. Cells were allowed to settle for 4 h, the gradient fractions checked microscopically, and fractions containing either pure blasts or pure small lymphocytes were pooled. Samples of each were washed three times in PBS, labelled with ^{125}I and extracted with Nonidet P-40, as described in Fig. 1. The remaining blasts were then cultured for 5 d in 50 ml Falcon tissue culture flasks, containing 10^7 cells in 10 ml EHAA medium, at 37°C in a 5% CO_2 atm, after which they were collected, washed three times, in PBS labelled with ^{125}I and extracts prepared as in Fig. 1. No blasts were evident in these 'reverted' cell cultures. The ^{125}I -labelled extracts were co-electrophoresed with ^{131}I -labelled extracts from nylon column purified T cells, as described in Fig. 1. *a*, Extracts of ^{125}I -labelled small lymphocytes from 1g gradient (\bullet) and ^{131}I -nylon wool cell extracts (Δ). *b*, Extracts of ^{125}I -labelled blast cells from 1g gradient (\bullet) and ^{131}I -nylon wool cell extracts (Δ). *c*, Extracts of ^{125}I -labelled reverted cells (\bullet) and ^{131}I -nylon wool cell extracts (Δ).

which is present in the spleen cell preparation is probably a B cell-associated protein, as it is greatly reduced in extracts made from cells passed through nylon wool columns (Fig. 1b), and is absent in macrophage and blast cell extracts.

Figure 2a and b shows the profiles of nylon separated lymphocytes compared with extracts of labelled small lymphocytes and blast cells, respectively, after separation on a 1g gradient from a 5-d-old MLC. Blast cells activated by allogeneic cells (Fig. 2b) have the three distinct peaks of molecular weights 200K, 187K and 170K, replaced by a broad band of radiolabelled proteins covering the molecular weight range of 170–200K. In addition, a new peak or greatly increased component of 94K has appeared and several changes in the intensity of other peaks have occurred. The small lymphocytes from the 1g gradient retain the three distinct peaks (200, 187 and 170K) present in the starting nylon column purified cells, as well as most of the other starting cell peaks.

In contrast to the blast cells, reverted cells (Fig. 2c) have three discernible peaks of radioactivity in the 170–200K molecular weight range. The 200K and 187K peaks are the same as the peaks in the nylon column purified cells, but the third peak (170K in the nylon column cells) is reproducibly broader and shifted to slightly higher molecular weight. There is an increase in the amount of the 200K peak in reverted cells compared to blast cells. In addition, the 94K peak in the blast cells is greatly reduced or missing from the reverted cells, while a peak of 70K is prominent in the reverted cells but not in the blast cells. In comparison to the starting nylon wool cells, the reverted cells have different proportions of the 170K, 187K and 200K peaks, and peaks of 70K and 90K have appeared which are absent or present in low amounts in the starting cells.

The experiments presented demonstrate that T cells obtained from the blast cell fraction of a 1g gradient that have undergone functional change after allogeneic stimulation have different cell surface ^{125}I -labelling patterns from those of a starting population of T cells obtained from nylon wool or small lymphocytes obtained from the 1g gradient. The differences are consistent with the surface differentiative changes which take place as a small lymphocyte develops into a blast cell. These changes, however, may be associated with the cell cycle or represent alterations in the accessibility to iodination of common components due to changes in other components. They may also reflect expression of new blast-specific surface structures or modification of molecules existing in the non-stimulated cell, for example, by glycosylation. Also, selection of a clonal type, where cells of different responding clones give rise to functionally similar blasts which have different surface patterns, can be ruled out because we have observed the same changes where stimulating cells from different strains were used (unpublished data). Further, one might not expect variation in the molecular weight (as measured in SDS) of a given membrane product in different clones of cells with the same function.

More difficult to evaluate is whether these changes could reflect selection, during culture, of one or more functionally distinct T cell subpopulations with the observed ^{125}I -banding patterns. We regard this as unlikely in view of our current understanding that the T cell subpopulations present and responding in the initial T cell population^{5,6} are the same as and occur in similar proportion (A. Senik & B. R. Bloom, personal communication) to those found in the blast fraction. The interpretation of our results as a selection process could be clarified if the starting population could be more specifically defined, by raising antisera to the proteins that differentiate the starting small lymphocytes, the blasts and reversion lymphocytes and using these sera to dissect the various populations.

The blast T lymphocyte population analysed on these gels consists of several functionally different T cell populations. The majority of T lymphocytes present in the blast cell fraction are probably proliferating helper T cells, while a small percentage are cytotoxic T lymphocytes, and some suppressor T lymphocytes may be present. We are undertaking further experiments to determine if these functionally different blast

cell populations also differ in their cell surface components.

Cyclophosphamide inhibited B cell receptor regeneration as a basis for drug-induced tolerance

A WIDE range of immunosuppressive agents can facilitate the induction of specific tolerance by thymus-dependent antigens. In the case of cyclophosphamide (CY), this involves T cells (including the generation of suppressor T cells), whereas B cells remain relatively unaffected^{1–3}. On the other hand, CY lowers the B cell tolerance threshold to thymus-independent (TI) antigens^{4,5}, a characteristic not shared by other alkylating agents (melphalan and chlorambucil) or immunosuppressive drugs (6-mercaptopurine, azathioprine and A-methopterin) (J. G. Howard and C. Hale, in preparation). Although high doses of CY induce selective depletion of B cells^{6,7}, its immunosuppressive potential *in vivo* or *in vitro* is manifest with doses well below this cytotoxic threshold (F. L. Shand, in preparation), which is not the case with melphalan and chlorambucil. Consequently, the B cell tolerance-promoting and reversible immunosuppressive activities of CY might be dissociable from its cytotoxicity. We have investigated the ability of splenic B lymphocytes from CY-injected mice to cap and subsequently regenerate their surface immunoglobulin (SIg) receptors following treatment with anti-immunoglobulin. Re-expression of B cell SIg was grossly impaired following treatment with CY, but not with other immunosuppressive agents. This finding provides a possible explanation for the increased susceptibility of B cells to tolerance induction with TI antigens.

Mice of both sexes from various strains (BALB/c, CBA/Lac, CBA/H and CBAx57BL)F₁ were used between 3 and 6 months of age. Cyclophosphamide monohydrate (Koch-Light), melphalan, chlorambucil and 6-mercaptopurine (Wellcome) were injected intraperitoneally at 150, 10, 30 and 75 mg per kg, respectively. Melphalan and chlorambucil were used at their maximally tolerated doses; in the case of CY, this exceeds 300 mg per kg. Spleen cell suspensions were treated with rhodamine-labelled rabbit-anti-mouse Ig (supplied by Dr L. Hudson) for 45 min at 37 °C. After three washes, 1×10^7 cells were cultured in Marbrook chambers and samples collected periodically for indirect immunofluorescent staining in 0.13% sodium azide using the (Fab')₂ fragment of rabbit-anti-mouse Ig (pre-

Fig. 1 Comparison of SIg receptor regeneration of spleen cells from normal (□) melphalan-injected (10 mg per kg) (○) or CY-injected (150 mg per kg) (△) mice, after treatment with anti-Ig serum. Spleen cells (2.5×10^7) were incubated in 0.5 ml of rhodamine-labelled rabbit-anti-mouse Ig serum (1/40) for 45 min at 37 °C. Suspensions were washed three times and 1×10^7 cells cultured in RPMI + 5% foetal calf serum in Marbrook chambers for 24 h at 37 °C in 5% CO₂. Cells were collected and stained in 0.13% sodium azide with an indirect immunofluorescence assay using a (Fab')₂ fragment of rabbit-anti-mouse Ig (1/20) followed by a FITC-labelled sheep-anti-rabbit Ig (1/20). The percentage of total lymphocytes expressing new FITC-labelled SIg was based on counts of 200–300 cells. Dashed lines represent the levels of SIg-bearing cells in control preparations which were not treated with rhodamine-labelled anti-Ig serum.

pared by pepsin digestion and fractionation on ultragel Ac-44) followed by fluorescein-labelled sheep-anti-rabbit Ig (Wellcome Reagents Ltd). This protocol enabled us to monitor both the frequency of capping and the reappearance of new SIg. The use of a (Fab')₂ fragment excluded the possibility of detecting Fc receptors. In enumerating those B cells which expressed new SIg, we recorded as positive only those cells which showed typical ring membrane fluorescence with fluorescein in the absence of rhodamine. Whereas normal spleen suspensions after anti-Ig treatment had levels of B cells expressing new SIg which were 40 and 75% of control values at 6 and 24 h respectively, a corresponding increase in B cells expressing new SIg was not detected in spleen suspensions from mice injected with

CY 20 h earlier (Table 1). This result was obtained consistently in four experiments. Although a 30% reduction in the number of B cells recovered from CY-injected mice was always found, the frequencies of cells capping were essentially similar in either type of suspension. The percentage viability of cells from CY-injected mice was only marginally reduced after 24 h of culture as compared with normal cells. Analogous impairment of SIg receptor regeneration has also been reproduced with normal spleen cells previously treated with CY activated by liver microsomes *in vitro* (F. L. Shard, in preparation). In other experiments, spleen cells from CY-treated mice were compared with those from normal or melphalan-treated mice. Figure 1 shows typical impairment of SIg regeneration in CY- but not melphalan-injected mice. In another experiment, neither chlorambucil nor 6-mercaptopurine caused any impairment of SIg receptor regeneration. Thus, the failure of B cells from CY-injected mice to regenerate their SIg receptors is a distinctive sequel to treatment with this drug not shared by the other immunosuppressive agents. To ascertain whether this abnormal behaviour of B cells 20 h after CY injection was a reversible phenomenon, spleen cells from mice injected with CY 1, 3 or 7 d previously were examined for their ability to regenerate SIg after anti-Ig treatment. Partial recovery of SIg regeneration was found 3 d after CY and full recovery by 7 d (Fig. 2a). The immune status of parallel groups of mice was established by challenge with either levan or sheep red blood cells at the same time intervals after CY treatment. The levels of SIg recovery correlated with the extent of immune response following challenge with both T-dependent and T-independent antigens at the same times (Fig. 2b). In a final variant of these experiments, the incubation

period after anti-Ig treatment was increased to 72 h, to determine whether or not the impairment of SIg regeneration was durable. No receptor regeneration of CY-treated B cells was observed even after 72 h of culture, despite cell viabilities which were comparable to those of control groups (Table 2).

It has been suggested that CY-induced tolerance involves death of lymphocytes triggered by antigen either because of a block in their normal differentiation sequence or a selective vulnerability of the S or G₂ phases of the cell cycle⁸. This view is weakened by the finding that CY promotion of tolerance with T-independent antigens depends on their tolerogenicity rather than immunogenicity (ref. 5 and J. G. Howard and C. Hale, in preparation). An attractive and likely alternative is that the B cell tolerance-promoting effect of CY is due to an impairment of SIg receptor regeneration following interaction with multivalent antigens, assuming that the sequelae are similar to those following anti-Ig interaction. The fact that other immunosuppressive drugs seem incapable of reproducing this effect and of promoting tolerance strongly supports such a view. Moreover, the finding that B cells from CY-injected mice containing endocytosed rhodamine-labelled anti-Ig were still abundantly present after 24 h of culture further substantiates a lack of cytotoxic deletion.

Anti-Ig treatment of immature B cells in foetal liver, neonatal spleen and adult bone marrow cells^{10,11} causes an irreversible disappearance of SIg which is not found with mature B cells. This may explain the ease with which immature B cells are tolerised by multivalent antigens¹⁰. A similar result has been obtained by the prolonged exposure of B cells to certain polymeric antigens^{11,12}. We suggest that CY induces a temporary reversion to a state of functional immaturity analogous to that of B cells in foetal or newborn mice, during which their interaction with antigen leads to tolerance alone. We are currently seeking further evidence of indissociability between impaired SIg receptor regeneration and reversible immunosuppression of B cells induced by CY, as well as the nature of the underlying metabolic events.

Specific immune response enhancing factor in serum of immunised mice

ONE of the central problems of immunology is the mechanism by which regulatory thymus derived T cells—T helper, T amplifier and T suppressor cells—interact with each other and with the precursor cells of the antibody-forming B lymphocytes. Various mediators produced by T cells acting directly or indirectly on B cells have been described. Some of these factors have been shown to enhance^{1–4} or to suppress^{5,6} the function of B cells either in an antigen-specific^{1,2,5} or in a nonspecific^{3,4,6} manner. Immune response-enhancing factors produced *in vitro* have been shown to replace T helper or T amplifier cell function in thymus-dependent antibody formation *in vivo*^{1,2} and/or *in vitro*^{1–4}. We show here that the serum (S₄) of mice injected 4 h previously with a super-optimal dose of sheep red blood cells (SRBC) contains an antigen-specific principle—specific immune response enhancing factor (SIREF)—which enhances the humoral immune response up to 60-fold when injected before a sub-optimal antigen dose into mice but not in mice injected with an optimal dose of antigen (2 × 10⁸ SRBC). SIREF could not be produced in athymic nude mice and SIREF produced in BALB/c (H₂d) or C57Bl (H₂b) mice acted in either strain, but not in athymic mice (Table 1). These results indicate that SIREF(1) may be released from T cells (or from B cells which require T-cell cooperation), (2) acts through the H₂ barrier, and (3) does not act directly on B cells.

As shown in Fig. 1, SIREF is antigen specific—if produced

Fig. 1 Antigen specificity of SIREF. BALB/c mice were injected i.v. with 10⁹ SRBC or 10⁸ HRBC (horse red blood cells). Serum collected 4 h later (S₄ SRBC or S₄ HRBC respectively) was injected i.v. (0.1 ml per mouse) in mice immunised with either SRBC (10⁵ SRBC per mouse i.v.) or HRBC (5 × 10⁴ HRBC per mouse i.v.). S₄ was given 2 h before the antigens. Controls were injected with either S₄ SRBC, S₄ HRBC, 10⁵ SRBC or 5 × 10⁴ HRBC. The IgM PFC in the spleen of the mice were detected 6 d later. Each value represents the mean of PFC per spleen detected in 6 animals on day 6. The vertical bars represent the standard deviation of the mean. HRBC-immunised mice were tested for anti-HRBC-PFC, SRBC immunised mice were tested for anti-SRBC-PFC. a, SRBC (10⁵); b, S₄ SRBC; c, SRBC (10⁵) + S₄ SRBC; d, SRBC (10⁵) + S₄ HRBC; e, S₄ HRBC; f, SRBC (5 × 10⁴) + S₄ HRBC; g, HRBC (5 × 10⁴) + S₄ SRBC; h, HRBC (5 × 10⁴) + S₄ SRBC.

in SRBC-injected mice SIREF enhances the immune response in SRBC immunised recipients but not in mice immunised with horse red blood cells (HRBC) and vice versa. The enhancing effect of S_4 HRBC was, however, significantly less marked than that found in animals receiving S_4 SRBC and SRBC. Rabbit anti-SRBC antibody bound covalently to Sepharose removed up to 90% of SIREF activity from S_4 SRBC (T.D. and H.N., in preparation). This finding again shows the specificity of SIREF and suggests that SIREF has to contain such antigenic determinants.

SIREF is not simply an antigen or an immunogenic degradation product of SRBC. This view is supported by the following findings: (1) 0.4 ml of S_4 derived from either strain of mice was even less effective than 0.1 ml of S_4 in enhancing the plaque-forming cell (PFC) response, (2) when injected alone 0.4 ml S_4 was no more immunogenic (280 ± 93 PFC) than 0.1 ml of S_4 (314 ± 119) as tested 6 d later and (3), serum derived from antigen-injected nude mice did not show significant SIREF activity.

SIREF does not alter the initiation of the immune response but enhances and prolongs the antibody formation (Fig. 2). The effect of the factor in the primary immune response is restricted to the IgM response. Preliminary experiments (data not shown) indicate that SIREF counteracts a mechanism which determines both the magnitude and persistence of the IgM response. A similar activity has been described by Henry and Jerne⁷, who obtained identical results injecting an active principle isolated from the serum of SRBC-immunised mice 4 d after immunisation. They claimed that the serum activity was due to IgM anti-SRBC antibodies present in their preparation. In our experiments, serum containing SIREF obtained 4 h after immunisation was completely free of anti-SRBC antibodies (as tested by anti-SRBC antibody titration) and SIREF could be detected (in a much smaller amount) up to 4 d after immunisation. We suggest that the 'regulation of the immune response by IgM antibodies' as proposed by Henry and Jerne should in fact, to accommodate our findings, be considered as 'regulation of the IgM response by SIREF'. This suggestion is further supported by the findings (1) that SIREF is not dialysable, (2) that in ammonium sulphate treatment of serum the

Fig. 2 Effect of SIREF on the kinetics of the IgM response. BALB/c mice 6–8 weeks old were injected with 10^8 SRBC; 0.1 ml serum collected 4 h later (S_4) was injected i.v., 2 h before immunisation of syngeneic animals with 10^6 SRBC i.v. Controls were injected with either S_4 or 10^8 SRBC i.v. At the times indicated direct IgM and indirect IgG PFC were assayed by the Jerne technique in the modification of Cunningham and Szenberg¹⁰ and as described in detail previously¹¹. Each point represents the mean of direct PFC detected in the spleens of 6 animals \pm standard deviation. IgG PFC could not be detected in either group of mice. Anti-SRBC hemolysine titers paralleled the PFC response presented here (Data not given here). ▲, S_4 +SRBC; ○, SRBC; ●, S_4 .

SIREF coprecipitates with the globulin fraction, and (3), SIREF was enriched in the conditions used by Henry and Jerne⁷ (H.N. and T.D., in preparation).

There are some similarities between SIREF and a serum factor described by Paraskevas *et al.*^{8,9}, who suggested that their factor is an antigen–IgM antibody complex released from B cells, cytophilic for a subset of T cells. This assumption was supported by the finding that spleen T cells derived from mice injected with SRBC 6 h previously and subsequently transferred into irradiated syngeneic animals enhanced the T cell-dependent IgG response (up to sevenfold) and the IgM response (up to two- to threefold) to SRBC. Paraskevas *et al.* assumed that at the time of the transfer the T cells were already armed with antigen–antibody complexes. SIREF, in contrast, does not affect the primary IgG response to either dose of SRBC but enhances dramatically (up to 60-fold) the IgM response when injected in normal animals immunised with a suboptimal antigen dose. Injection of SIREF does not induce immunological memory but injection of SIREF with a suboptimal dose of antigen induces development of memory cells of IgG type in a much higher amount than injection of the animal with the antigen alone (data not shown).

Several questions remain to be clarified: (1) is SIREF identical with Henry and Jerne's factor believed at that time to be IgM anti-SRBC antibody? (2) Is SIREF identical with the serum factor of Paraskevas *et al.*, and the discrepancies detailed above due only to differences in the ability to produce and/or to test the factor activity? (3) Are the three factors essentially identical, but according to our data released from T cells (T cell–receptor antigen complex) rather than from B cells (antigen–antibody complex)? The similarities in the production of SIREF, the factor obtained by Henry and Jerne or by Paraskevas and Lee and the finding that SIREF could not be produced in mice lacking functioning T cells (nude mice) seem to support the latter possibility. However, the contribution of

Transfer of the marker for morphologically transformed phenotype by isolated metaphase chromosomes in hamster cells

IN spite of extensive investigations of the process of carcinogenesis *in vitro*, the basic mechanisms of the primary events are poorly understood¹. In general, it is found that the first manifestation of the transformed phenotype involves morphological alteration of the cells. This is usually followed by an ill-defined process resulting in several further changes in phenotype including the ability of the cells

metaphase chromosome⁴⁻⁹. Most of the initial work was done with the genes for hypoxanthine phosphoribosyl transferase and thymidine kinase, but dominant markers such as resistance to methotrexate and ouabain can also be so transferred⁹, as can the wild-type alleles for three auxotrophic markers¹⁰. In seeking to delineate the genetic elements of carcinogenesis, we have examined the ability of purified metaphase chromosomes from Chinese hamster ovary (CHO) cells to transfer the first recognisable phenotype observed during cell carcinogenesis, that is, morphological transformation. Because of the low frequency of chromosome transfer, an appropriate method for selection of cells (transferees) which have incorporated the relevant markers from the background of recipient cells is necessary. Our experiments were based on the assumption that if transformation gene(s) could be transferred to senescent cells, then they should be able to produce colonies, whereas the majority of the cells which do not receive the appropriate marker, will not form colonies. The results presented here show that senescent hamster cells can be rescued and become transformed by transfer of purified metaphase chromosomes from CHO cells; the frequency of this event is similar to that of single gene markers.

Primary Chinese hamster lung cells were subcultured through five generations, and cloned. When the cloned cultures had reached confluence (~ 15 further generations), they were split into two subcultures, in 100-mm plates, and grown again. At the end of this time the cells were growing slowly, and were obviously in senescence. As might be expected, each clone gave rise to different numbers of cells at this stage. Nevertheless, in this way, a number of sets of two plates, each pair containing similar numbers of cells at the same level of senescence, were available as recipients. Purified metaphase chromosomes were isolated from CHO cells and aliquots added to one plate from each clone, as previously described^{2,9}. The plates were incubated at 37 °C in α -medium¹¹ containing 15% FCS for 2 d. Cells were then trypsinised, counted, replated in the same

to grow in agar (aga⁺), and to produce tumours in animals. In part because of the variety of phenotypes observed, but also because of the lack of suitable methods of analysis, it has been difficult to examine the process of transformation at the genetic level. We have recently initiated experiments designed to use chromosome transfer techniques to attempt such a genetic analysis^{2,3} and work in several laboratories has shown that single gene markers can be transferred from cell to cell at frequencies of 10^{-6} - 10^{-7} by means of the

medium and incubated at 37 °C for 3 weeks. Colonies were then counted and isolated using a stainless steel cylinder and trypsinisation. The results of the first such experiment are presented in Table 1 which shows that colonies were obtained in five of the six cultures treated with metaphase chromosomes (line 1), whereas no colonies were obtained when the senescent cells were plated without previous addition of metaphase chromosomes (line 2). No colonies were obtained when metaphase chromosomes were

added to the plates in the absence of recipient cells (line 3). The results of a similar experiment, with two additional controls, are shown in Table 2. Again, colonies were obtained when CHO chromosomes were added to the senescent cells (line 1) and no colonies were found in the absence of chromosomes (line 4) and in the absence of recipient cells (line 5). We also prepared metaphase chromosomes from two primary strains developed from Chinese hamster lung and Chinese hamster ovary, both in their sixth transfer passage (1:4 splits), CHLP6 and CHOP6, respectively. As may be seen in Table 2 (lines 2 and 3), these chromosomes were also unable to rescue senescent cells.

The experiments described in Tables 1 and 2 provide strong evidence that CHO metaphase chromosomes can rescue senescent cells. Figure 1 shows the morphology of clones from two of these transferent clones, as well as that of the donor and primary recipient cells. It is clear that the rescued cells have been altered morphologically and have the appearance of transformed cells. This transformed phenotype is maintained on continued culture of these clones. Four of the transferents were karyotyped in detail with trypsin-Giemsa banding. Of 26 cells examined, 60% had a normal diploid karyotype, 15% showed loss of one or more chromosomes, and 25% showed structural rearrangements.

spontaneous transformation in the recipients, and also tend to rule out any mechanism of 'induction' of transformation in recipients due to addition of chromosomal material.

The frequency of appearance of transferents in all of the experiments (Tables 1-3) is similar to that observed for a variety of single gene markers^{2,9,10}. This fact, in addition to the localisation of the activity to one size class argues for the view that the transformation of recipient cells by metaphase chromosomes is caused by the transfer of a single gene.

Although the transferent cells obtained in these experiments show a transformed morphology, we have found that they do not form colonies in agar (aga⁻) or tumours when injected into recipient animals², but they can be converted into cells which do form colonies in agar (aga⁺) and which can produce tumours in animals, by a second addition of CHO metaphase chromosomes, and appropriate selection². It has not been possible to produce aga⁺ cells directly by addition of CHO chromosomes to primary cells. In terms of their ability to be converted to aga⁺, the primary transferents behave identically to cells which have been transformed by benzo(a)pyrene, or cells which have transformed spontaneously in culture². These results provide further confirmation that the rescued senescent cells are transformed, and that a gene involved in a first step in

*. † and ‡ as in legend of Table 1.

From these results, we conclude that the addition of CHO metaphase chromosomes to senescent cells provides genetic information resulting in the transformation phenotype, and in rescue of senescence. Further support for this view has come from an experiment with fractionated chromosomes. Previously, we showed that metaphase chromosomes could be separated into three size classes in sucrose gradients (large A, medium B, small C), and that individual markers could be localised to specific size classes^{9,10}. Metaphase chromosomes from CHO cells were fractionated in this way, and each fraction was tested for the ability to rescue senescent recipient hamster cells. As may be seen in Table 3, lines 1-3, activity was found in the large size (A) class of chromosomes but few or no colonies were obtained with the other fractions. As before, no colonies were obtained in the absence of chromosomes (line 4) or recipient cells (line 5). Transferent colonies obtained in this experiment were also transformed in phenotype.

Thus, the ability to transform cells behaves similarly to other genetic markers and can be located on a specific size class of chromosomes.

The negative findings with the B and C chromosome size classes provides further evidence that the transformed colonies obtained result from addition of donor chromosomal material, rather than

transformation has been identified. The successful isolation of such transferents also provides evidence that this gene acts dominantly. Our results do not, however, show that this is the only gene involved in the primary transformation step. Further experiments involving a variety of donors, and recipients, will be required to examine questions of this kind.

Dr R. Worton provided useful comments on the manuscript, in addition to help with the analysis of the karyotypes; Miss Nancy Stokoe provided technical assistance. Deficient recovery from potentially lethal radiation damage in ataxia telangiectasia and xeroderma pigmentosum

THE enhanced survival that occurs when mammalian cells are maintained in a density-inhibited state for a short time after treatment with X rays, ultraviolet light or drugs has been termed potentially lethal damage repair (PLDR)¹⁻³. It is analogous to liquid-holding recovery in bacteria and yeast, and has been studied using a variety of agents in different cell lines³⁻⁵ and in malignant tumours^{6,7}. To investigate the relationship between this cellular recovery phenomenon and repair at the molecular level, we have examined PLDR in human diploid cell strains with known molecular repair defects. We report here that xeroderma pigmentosum (XP) skin fibroblasts show no PLDR following ultraviolet light irradiation, whereas ataxia telangiectasia (AT) skin fibroblasts are specifically deficient in PLDR following X-ray irradiation. The results suggest that, as in bacterial cells, this cellular recovery phenomenon does reflect molecular DNA repair—probably the excision repair pathway.

XP is an autosomal recessive disease characterised by extreme sensitivity to ultraviolet light and leading to the development of multiple malignant skin tumours. Skin fibroblasts from these patients show a deficiency in the excision repair of ultraviolet light-induced DNA base damage⁸. Five complementation groups designated A to E, as well as a variant group of XP patients, have been identified. AT is an autosomal recessive disease characterised by cerebellar ataxia, telangiectasia of the bulbar conjunctiva and a predisposition to malignant tumours, especially of the reticulo-endothelial system. When treated for malignancy by irradiation, AT patients have in some cases demonstrated a clinical radiosensitivity. Also, skin fibroblasts derived from these patients are unusually sensitive to X rays *in vitro*⁹ and a defect in the repair of gamma irradiation induced DNA damage has been described in some strains¹⁰.

We have examined the capacity of skin fibroblast cell strains derived from patients with XP and AT to perform

PLDR following either ultraviolet light or X-irradiation. The results were compared with those for a normal diploid fibroblast cell strain. PLDR refers to the enhancement in cell survival which occurs in density-inhibited plateau phase cultures when assay for the surviving fraction by subculture at low density is delayed for several hours after irradiation¹.

The D_0 (inverse of the slope) values of the survival curves following irradiation of these cell strains in exponential growth are shown in Table 1. As previously reported⁹, AT was markedly more sensitive to gamma irradiation than either the normal strain (Li 106) or the XP (A) strain. XP strains A and C, however, were significantly more sensitive to ultraviolet light than either AT or Li 106. Figure 1 shows the results of X-ray PLDR experiments in which Li 106, AT and XP fibroblasts were irradiated in the density-inhibited plateau phase of growth; following X-ray irradiation, cells were subcultured at regular time intervals over 0-24 h to assay for colony forming ability. Doses were chosen to yield approximately the same surviving fraction. Recovery in Li 106 and XP cells is manifested by a maximum increase in survival of 4- and 5-fold, respectively (Fig. 1). In the case of X-ray repair deficient AT cells, however, maximum recovery was by a factor of 1.5, at a survival level considerably lower than for XP or Li 106 (Fig. 1). As the enhanced survival in PLDR is associated with a change in the slope of the survival curve, one would expect a greater increase in PLDR at lower survival fractions¹.

Figure 2 shows the results of ultraviolet light PLDR experiments in which the normal, XP (group A), and AT cells were irradiated in the density inhibited state, then subcultured 0-32 h later. Recovery in the AT and normal cell strains was approximately 3-fold and 5-fold, respectively, in this experiment (Fig. 2); ultraviolet light-induced PLDR took place more slowly than X-ray PLDR (Fig. 1) as is also the case for molecular (excision) repair following the two types of radiation. There was no recovery in the XP strain; the slight decline in survival seen with short recovery intervals was a consistent finding. Ultimate recovery ratios representing the results of at least three separate experiments for each cell strain following X-irradiation and ultraviolet light are shown in Table 1. No recovery was observed in XP cells from complementation groups A and C following exposure to ultraviolet light, and recovery was significantly reduced in X-irradiated AT cells. Thus, cells which are deficient in the excision repair of ultraviolet light damage did not perform PLDR following ultraviolet light exposure, and X-ray repair deficient cells (AT) seem to have a markedly reduced capacity for PLDR following X-ray exposure. The results with Li 106 are

Table 1 Radiation sensitivity and repair of potentially lethal damage in human diploid fibroblast strains

Cell strain and source	Clinical classification	Cloning efficiency	D_0 (X ray)	Enhancement after X ray	Survival D_0 (ultraviolet light)	Survival enhancement after ultraviolet light
Li 106 (Primary culture)	Normal skin fibroblasts	1.0-6.3%	149±7	4.13±0.03	31±6	4.33±0.34

XP4BE (ATCC CRL 1162)	XP skin fibroblasts (variant)	0.7-1.2%	—	—	20±2	2.30±0.40

D_0 is inverse of slope of complete survival curve; exponentially growing cells were trypsinised, seeded at appropriate numbers into triplicate 10-cm plastic dishes, and irradiated 18 h later. The D_0 values were derived from least squares linear regression analysis of at least three experiments. PLDR experiments were carried out as described in Figs 1 and 2. Numbers represent mean survival enhancement ±1 s.e.m. in at least three separate experiments for each cell strain (two experiments for XP (c) and XP variant strains determined after 6 h for X-irradiation and after 24 h for ultraviolet light irradiation).

characteristic of those with five normal human diploid fibroblast strains tested concurrently in our laboratory.

XP variant cell strains show near normal sensitivity to cell killing by ultraviolet light and a normal excision repair capacity, but an apparent deficiency in a post-replication repair process¹¹. The results of ultraviolet light PLDR experiments carried out with an XP variant strain are also shown in Table 1. While groups A and C XP cells were deficient in excision repair, the variant cells were able to carry out PLDR following ultraviolet light irradiation.

We have demonstrated that cells deficient in molecular repair following X-ray (AT) or ultraviolet light (XP) exposure are similarly defective in PLDR. This report is the first to correlate specific DNA repair defects with impairment of a cellular recovery process in mammalian cells. The results suggest that PLDR as a general phenomenon in density-inhibited cells reflects molecular repair processes, which in turn are reflected by an increase in survival. Furthermore, the fact that XP variant cells can perform PLDR while other XP cells cannot suggests that ultraviolet light induced PLDR may specifically reflect the excision repair pathway.

Both AT and XP patients have a predisposition to develop malignancies, and deficiencies in these particular repair systems may be relevant to this susceptibility. Actively proliferating cells in renewal systems may turn over and be lost from the body before they express neoplastic development. However, spontaneous or induced DNA damage in resting stem cells might be repaired mainly by mechanisms such as those reflected by PLDR. These mechanisms appear to act particularly efficiently in non-proliferating cells. Since the stem cell is the likely target as the origin of neoplastic development, deficiencies

Fig. 1 Repair of X-ray-induced potentially lethal damage ○, Li 106 normal skin fibroblasts ●, CRL 1223, skin fibroblasts from a patient with xeroderma pigmentosum (complementation group A); ▲, CRL 1343, skin fibroblasts from a patient with ataxia telangiectasia. Cultures were maintained at 37 °C in Eagle's minimal essential medium (Gibco F-15) supplemented with 15% foetal calf serum (Microbiological Associates), D-glucose (900 mg l⁻¹), sodium pyruvate (0.66 mg l⁻¹) and chlortetracycline (Aureomycin, Lederle, 50 µg ml⁻¹) in a 5% CO₂ atmosphere. Cells from each strain were studied at similar passage levels in cultures (ranging from the 4th to 28th mean population doubling). Cells were grown to confluency in 6-cm dishes. The culture medium was renewed daily for 3 d after initial confluency and the experiment was performed on the 4th day. Plates were irradiated at room temperature with a 220 kVp GE Maximar unit operated at 15 mA with a dose rate of 80 rad min⁻¹. XP and normal fibroblast cultures were given 700 rad, AT cultures 350 rad. Following irradiation, plates were returned to the incubator. Single plates were removed from the incubator at regular time intervals, trypsinised (0.25% trypsin in Ca²⁺ and Mg²⁺-free Earle's balanced salt solution), and cells seeded in 10-cm dishes in triplicate. The number of cells seeded per dish ranged from 20,000 to 40,000, depending on cell strain and experimental conditions. Medium was changed after 7 d, and after approximately 14 d, cells were fixed, stained with 0.5% methylene blue and scored. Colonies containing 50 or more cells were scored as survivors. The figure depicts a single representative experiment. S, Number of cells surviving at a given time; S₀, number of cells at zero time.

Fig. 2 Repair of ultraviolet light induced potentially lethal damage ○, normal skin fibroblasts; □, AT fibroblasts; ● XP fibroblasts. Cultures were maintained and grown to confluency as described in Fig. 1. On the 4th day, cultures were rinsed with Earle's Balanced salt solution, the solution removed, and the cultures irradiated with a 254 nm light source at a dose-rate of 4.5 erg mm⁻² s. Normal and AT cultures were exposed to 120 erg mm⁻², XP cells 20 erg mm⁻² except XP variant (60 erg mm⁻²). Following irradiation, conditioned medium was added, and the dishes returned to the incubator. Cultures were trypsinised at regular intervals and cells seeded into 10-cm dishes in triplicate. The dishes were maintained, fixed, stained and scored as described in Fig. 1.

in a repair process which is usually thought to be error free (excision-repair) might lead to the accumulation of mutational damage in the DNA and lead to the ultimate expression of malignant change.

We suggest that AT cells are deficient in X-ray PLDR while XP cells are deficient in ultraviolet PLDR, and that this cellular recovery phenomenon reflects molecular repair processes. Deficiencies in this type of repair may contribute to the general predisposition to the development of malignancies in these patients.

Butyric acid suppression of the *in vitro* neoplastic state of Syrian hamster cells

BUTYRIC acid has been shown to induce morphological and biochemical differentiation in a variety of cells in culture¹⁻⁸. Although the mechanism of action of this short chain fatty acid remains to be understood, changes induced by butyric acid have included: (1) growth inhibition and morphological alterations in HeLa cells, Chinese hamster ovary cells, and neuroblastoma cells²⁻⁴; (2) increases in tyrosine hydroxylase activity and adenylate cyclase activity in neuroblastoma cells^{1,3}; (3) induction of erythroid differentiation in erythroleukaemic cells⁶; and (4) induction of functional β -adrenergic receptors in HeLa cells^{7,8}. We reasoned that the

induction of these differentiated functions might be associated with a concomitant suppression of neoplastic properties. Therefore, we have investigated the effects of butyric acid on the aberrant morphology, anchorage-independent growth, and enhanced fibrinolytic activity of a highly tumorigenic Syrian hamster fibroblast cell line, BP6T (refs 9, 10). We have found that butyric acid causes reversible, specific suppression of each of these altered *in vitro* properties frequently associated with neoplasia. This system could be of value for the investigation of the mechanism of the cellular control of the neoplastic state.

We studied the effects of butyric acid on BP6T cells and two clonal isolates, BP6T-But 1 and BP6T-But 2, derived from BP6T cells. These two clonal strains were obtained by single colony isolation following two subculturings in medium supplemented with 2 mM butyric acid (final pH 7.2), and maintained in this medium unless otherwise stated. The addition of butyric acid to the culture medium produced a slight decrease in the growth rate and cloning efficiency of BP6T cells. Table 1 summarises the growth properties of BP6T cells and the two clonal isolates in unsupplemented medium and in medium containing butyric acid. Butyric acid slowed the doubling time by 4–7 h, and reduced the cell saturation density 20–70%, although the degree of response differed among the three cell strains. These suppressive effects on growth were reversed on removal of the butyric acid (Table 1). Since the tumorigenic BP6T cells exhibit a high plating efficiency on solid surfaces in liquid medium at low cell density, we investigated the effects of butyric acid on this property. BP6T, BP6T-But 1, and BP6T-But 2 cells were reduced in their abilities to form colonies when inoculated at 100 cells per plate in liquid medium containing butyric acid (Table 1). The cloning efficiencies ranged from 14% to 25% in medium containing butyric acid, contrasting with cloning efficiencies of 65–85% in normal medium. Although a diminution of the cloning efficiency resulted from the addition of butyric acid, the efficiency of cloning achieved for all three strains

remained much greater than that obtained with untransformed Syrian hamster embryo cells, which require plating densities of greater than 10^3 cells per 100-mm dish to produce any colonies.

In contrast to the mild effect on the general growth properties mentioned above, butyric acid added to culture medium produced profound effects on the colonial morphology, anchorage-independent growth, and fibrinolytic activity of BP6T cells. The random, criss-crossed orientation of spindle-shaped cells within a BP6T colony grown in the absence of butyric acid (Fig. 1a) is characteristic of Syrian hamster fibroblast lines transformed *in vitro* by chemical carcinogens^{11–14}. Dramatic alterations in this morphology were elicited in BP6T cells by a supplement of 2 mM butyric acid. In medium containing butyric acid, all colonies displayed morphologies similar to BP6T-But 1 and BP6T-But 2 (Fig. 1b and 1c), in that individual cells had a lower nuclear-cytoplasmic ratio and were orientated in a uniform, parallel pattern within the colony. This colony morphology is similar to that of untransformed Syrian hamster cells^{11–14}. To test the reversibility of this change, we plated cells of BP6T-But 1 and BP6T-But 2 into medium lacking butyric acid. In both cases, the transformed morphology of the colonies was restored.

The effect of butyric acid on anchorage-independent growth was examined by cloning in semi-solid agar^{9, 12, 15}. Following growth for 10 d in medium lacking butyric acid, BP6T cells form colonies at 50% efficiency following suspension of 200 cells⁹. When suspended in agar supplemented by 2 mM butyric acid at concentrations of 10^5 cells per plate, BP6T, BP6T-But 1, and BP6T-But 2 cells were unable to form colonies (Table 1). In contrast to its mild effect on cloning efficiency in liquid medium, butyric acid significantly inhibited anchorage-independent colony formation. To test the stability of the suppressive effect of butyric acid on anchorage-independent growth, the two clonal isolates were grown through 14 passages (approximately 54 population doublings) in liquid medium containing butyric

Table 1 Reversible effect of butyric acid on growth properties of Syrian hamster fibroblasts

Syrian hamster embryo cells	0	14	2.0	2–6	< 0.001 (10 ⁵)

*BP6T, a tumorigenic Syrian hamster fibroblast line, was derived from a fibrosarcoma which formed in a newborn Syrian hamster following injection of cells of a benzo(a)pyrene-transformed Syrian hamster fibroblast line. Experiments were conducted with BP6T cells 4–15 *in vitro* passages following tumour isolation. BP6T sublines BP6T-But 1 and BP6T-But 2 were isolated from BP6T cells grown in the presence of an exogenous supplement of butyric acid (2 mM, pH 7.2) for two passages. Colonies which formed following plating of 50 BP6T cells into 100-mm plates containing butyric acid-supplemented medium were isolated and grown continuously in that medium. Syrian hamster embryo cells were derived from 11-d-old embryos; their growth properties and fibrinolytic activities were measured between passages 4 and 8 inclusive. Cell culture procedures used have been described previously^{9, 10}.

†The population doubling time was measured during exponential growth at cell densities 1/10 of the cell saturation density for each line. Cell saturation densities were determined in 25 cm² tissue culture flasks (Falcon). For the measurement of population doubling time and cell saturation density in the absence of butyric acid, cells from BP6T-But 1 and BP6T-But 2 were measured one passage following removal of the compound.

‡The cloning efficiency was determined by plating 100 cells into 100-mm × 20-mm (Falcon) optilux polystyrene dishes in 10 ml of medium with or without butyric acid (2 mM). Colonies which formed after 10–14 d were fixed, stained with Giemsa, and counted. The cloning efficiencies are expressed as percentages of the number of cells plated. The cloning efficiency of Syrian hamster embryo cells was determined using 0.5×10^4 – 2×10^4 cells as an initial inoculum.

§Anchorage-independent colony formation was measured by suspending cells in semi-solid agar medium containing 0.4% Difco bacto agar, 0.1% bacto-peptone, and 10% foetal calf serum dissolved in culture medium⁹. Suspended cells were incubated for 14 d to allow colony growth. The colony-forming efficiencies are expressed as percentages of the total number of cells suspended; the figures in parentheses are the number of cells suspended in each dish.

Fig. 1 Effect of butyric acid on colonial morphologies. *a*, BP6T colony formed in the absence of butyric acid, fixed and stained with 10% aqueous Giemsa; *b*, BP6T-But 1 colony (P12) formed in the presence of 2 mM butyric acid; *c*, BP6T-But 2 colony (P 12) formed in the presence of 2 mM butyric acid. All magnifications are $\times 40$.

acid. Following suspension of 10^5 BP6T-But 1 cells in agar containing 2 mM butyric acid, no growth was observed. In contrast, BP6T-But 2 cells partially regained the capacity for anchorage-independent growth, forming 150 colonies following suspension of 2.5×10^4 cells in agar containing 2 mM butyric acid. These results indicate both the stable nature of the suppression of anchorage-independent growth in the presence of butyric acid, and the possibility of obtaining strains which are resistant to this suppressive effect. The suppression of anchorage-independent growth was, however, reversed following removal of the butyric acid supplement. Omission of butyric acid from the culture medium and cultivation of BP6T-But 1 and BP6T-But 2 cells through two passages (approximately eight population doublings) resulted in near restoration of the anchorage-independent cloning efficiency to that of BP6T cells (Table 1).

Previous investigations have indicated that both the variant morphology of transformed lines, and anchorage-independent growth *in vitro* depend on cell-mediated fibrinolytic activity¹⁶⁻¹⁸. Quantitative assays of fibrinolysis have been used to measure the cellular production of the proteolytic factor, plasminogen activator, which cleaves plasminogen to its enzymatically active fibrinolytic form, plasmin^{10,19}. Elevated plasmin-mediated fibrinolysis is a property of BP6T cells and other tumorigenic Syrian hamster cell lines, but not of early passage Syrian hamster embryo cells^{10,16,17}. We examined the effect of butyric acid on both extracellular fibrinolytic activity, present in medium incubated with cells, and on intracellular fibrinolytic activity, present in cell lysates (Table 2 and Fig. 2). Fibrinolytic activity was measured by the extent of degradation of insoluble ^3H -fibrin to soluble ^3H -fibrinopeptides in a cell-free assay¹⁰. BP6T cells exhibited high levels of extracellular fibrinolytic activity, whereas BP6T-But 1 and BP6T-But 2 cells grown in the presence of 2 mM butyric acid produced low levels of extracellular activity, reduced by 85–95% compared with BP6T cells (in the absence of butyric acid) following growth of BP6T-But 1 cells for three passages (approximately 12 population doublings) in medium lacking butyric acid, however, the extracellular activity increased to 40% of the activity of the BP6T cells.

BP6T cells grown for 48 h in medium supplemented with 2 mM butyric acid exhibited an 80–90% reduction in intracellular fibrinolytic activity (Fig. 2). BP6T-But 1 cells grown

in the presence of butyric acid for 14 passages also exhibited reduced intracellular fibrinolytic activity (70–80% reduced compared with BP6T intracellular activity). Following cultivation of BP6T-But 1 cells through three passages in medium lacking butyric acid, the level of intracellular fibrinolytic activity in this strain rose to a level comparable with that of the parent BP6T cells. During this period, the capacity for anchorage-independent growth was restored (Table 1).

Aberrant morphology, anchorage-independent growth, and enhanced proteolytic activity are *in vitro* cellular properties which have been correlated with tumorigenicity.

Fig. 2 Reversible effect of butyric acid on intracellular fibrinolytic activity. The fibrinolytic activity in cell lysates was measured by the method of ^3H -fibrin degradation as described previously¹⁰. (One unit of fibrinolytic activity is as defined in Table 2). Results represent the means of duplicate determinations, following subtraction of radioactivity released by buffer alone (background). ●, BP6T cells; ○, BP6T cells cultured 48 h in the presence of 2 mM butyric acid; □, BP6T-But 1 cells cultured in the presence of 2 mM butyric acid; ■, BP6T-But 1 cells, butyric acid removed for 12 population doublings; ▲, Syrian hamster embryo cells, passage 3.

Table 2 Reversible effect of butyric acid on the fibrinolytic activities of Syrian hamster fibroblasts

Cell type	Butyric acid concentration (mM)	Extracellular fibrinolytic activity* (units per 2 ml culture medium)
Control (no cells)	0	3.1
Syrian hamster embryo cells	0	3.2
BP6T	0	4.2
BP6T-But 2	2	4.2
BP6T-But 1	2	6.1
BP6T-But 1	0	16

*The procedure for measuring extracellular fibrinolytic activity by the technique of ^3H -fibrin degradation has been described¹⁰. One unit of fibrinolytic activity is defined as that which solubilises 10% of the radioactivity release by 100 units of urokinase in 2 h at 37 °C. Values for extracellular activity represent the total units of fibrinolytic factor present in 2 ml of medium cultured in the presence of cells. The background activity observed with control culture medium (which was not incubated with cells) was 3.1 urokinase unit equivalents. The averages of duplicate determinations are reported. Addition of 2 mM butyric acid to medium from BP6T cells cultured in the absence of butyric acid had no significant effect on the extracellular enzyme activity.

The molecular processes, however, which control the expression of these phenotypes are not well understood. One approach toward defining these processes is to regulate the expression of specific phenotypes through the application of exogenous agents. Our results demonstrate that the expression of aberrant colony morphology enhanced fibrinolytic activity, and anchorage-independent growth can be regulated in transformed Syrian hamster cells by the addition of butyric acid to culture medium. Control experiments have shown that butyric acid has no effect on the protein concentration of cell lysates or the activities of two unrelated enzymes, hypoxanthine phosphoribosyltransferase and adenine phosphoribosyltransferase, which are extracted by the same procedure^{20,21} (data not shown). This suggests that the effects we have observed may reflect some degree of specificity of the action of butyric acid. As these phenotypic alterations can be observed during relatively short periods, kinetic analyses of the appearance and disappearance of specific cellular properties following the addition or removal of butyric acid should enable a determination of their interrelationships. An extension of these preliminary studies to an examination of changes in messenger RNA, proteins, and other macromolecules synthesised during the phenotypic reversals, and a determination of the mechanism of action of butyric acid may lead to a better understanding of cellular mechanisms regulating the neoplastic state.

Actin filaments form the backbone of nemaline myopathy rods

NEMALINE myopathy, a congenital neuromuscular disease, is one of several muscle disorders in which apparently abnormal Z lines, or Z line-type structures emanating from Z lines, has been described¹⁻⁶. There has been considerable speculation concerning the chemical composition and structural arrangement of proteins in nemaline rods^{2,4,7-12}, but these features have remained unclear: part of this uncertainty is related to lack of understanding of the intact Z line. The only Z line constituent for which there is substantial evidence is α -actinin¹³⁻¹⁶. We have described the preparation and properties of a Ca^{2+} -activated neutral protease (termed CAF) from muscle that is highly specific in its activity towards myofibrillar proteins and structure^{17,18}. Addition of CAF to isolated myofibrils or to teased muscle fibrils releases undegraded α -actinin from the Z line, with no noticeable effect on myosin, actin, or the remaining myofibrillar structure. We report here the use of CAF as a dissection tool to strip away the dense, amorphous component of the nemaline rods, exposing an underlying set of longitudinal filaments running parallel to the long axis of the original rod. Decoration of these filaments with heavy meromyosin¹⁹ shows that the longitudinal filaments of nemaline rods are composed of actin.

Skeletal muscle containing nemaline rods was obtained by biopsy from a patient with congenital rod disease (second biopsy, case No. 1; see ref. 20 for clinical details) and stored at -60 °C until glycerination. It has been shown previously that glyceration does not alter fine structure of the rods^{7,12}. Typical morphology of the muscle consists of areas which contain rods with associated thin filaments interspersed with areas of myofibrils containing moderately widened Z lines (Fig. 1a). Rods are often found grouped together and frequently seem to be branched. There are thin filaments continuous with the longitudinal lines of the rod, as has been described previously^{7,12}. Small numbers of thick filaments usually surround the rod bodies, but are not continuous with it. The longest rod shown in Fig. 1a was 4.3 μm long; many locations in all sections sampled contained rods from ~2 to 6 μm long, and all rods demonstrated the five characteristic features described by Engel²¹. In particular, the rods display a set of periodic (140 Å) longitudinal lines running parallel to their long axis; they also show periodic (345 Å) lines perpendicular to their long axis.

A teased, glycerinated nemaline fibre treated extensively with CAF is shown in Fig. 1b. Digestion with CAF removes dense material of the Z line as reported previously; it also removes seemingly dense material from the rods and exposes longitudinal filaments with a uniform diameter (60-70 Å) which span the lengths of the original rods. Thus, their length is dependent on the length of the original rod. Removal of the dense, amorphous material coincides with disappearance of the perpendicular periodicity in the rods. The exposed longitudinal filaments are not as straight as the parallel longitudinal lines present in the original rods, presumably because of loss of supporting material along

their perpendicular axis. As a result, they often can be seen to associate with each other. Stromer *et al.*¹² observed a similar loss of straightness in longitudinal filaments of nemaline rods surviving extended (40 d), low ionic strength extraction.

Because the long, exposed filaments resemble thin filaments in diameter, because thin filaments run into or at least up to the edge of rods in their intact state^{7,12,21} (Fig. 1a), and because of the similarity in resistance to CAF shared by thin filaments¹⁸ and these filaments (Fig.

Fig. 1 *a*, Electron micrograph of a longitudinal section of nemaline muscle. Thin strips of muscle were glycerinated as described¹⁹. After thin sectioning, fibres were prefixed with 3% glutaraldehyde, postfixed in 1% osmium tetroxide, and embedded in Epon-Araldite. Sections were stained with uranyl acetate, followed by lead citrate, and examined in an RCA-EMU-4 microscope operated at 100 kV. Note the large rod body with its long axis parallel to the adjacent myofibril. Longitudinal lines parallel to the long axis of the rod are very evident. M, M line; Z, Z line. *b*, Electron micrograph of a longitudinal section of nemaline muscle after CAF treatment. Teased fibres from glycerinated muscle were incubated with CAF (0.16 mg ml⁻¹) in the presence of 66 mM KCl, 33 mM Tris-acetate, pH 7.5, 3.3 mM CaCl₂, 6.6 mM 2-mercaptoethanol, 0.36 M sucrose, 0.6 mM NaN₃, at 25 °C for 30 min. To ensure complete digestion and removal of amorphous material, the incubation mixture was removed and replaced by fresh CAF mixture four times (30 min each). Following the fifth incubation, the CAF-treated fibres were washed twice in the same solution, except that 10 mM EGTA was substituted for the CaCl₂, and no enzyme was added. Note removal of material in the Z line and appearance of filaments of uniform diameter running throughout the area occupied by the original rod bodies. Small numbers of thick filaments, originally surrounding the rods, also can be seen in scattered clumps in this section. Control experiments (not shown) did not show any morphological changes when CAF was deleted from the incubation mixture. *c*, Electron micrograph of a CAF-treated nemaline sample incubated with heavy meromyosin (HMM). An equal volume of HMM (4 mg ml⁻¹) in 67 mM potassium phosphate buffer, pH 7.0, was mixed with an aliquot of the CAF-treated fibres suspended in the EGTA washing solution and gently stirred for 1 h at 25 °C. Excess HMM was removed by four washes with EGTA washing solution. Note that the long exposed longitudinal filaments bound the HMM to form well known¹⁹ arrowhead structures (compare *b* with *c*). At present it is difficult to determine the direction of polarity of each filament, but analysis of many sections indicates that adjacent filaments often have opposite polarity. Control experiments (not shown) showed no binding of material to filaments when HMM was deleted. Bar: 0.5 μm, photographs × 16,800.

1b), samples of CAF-treated nemaline fibres were incubated with heavy meromyosin. In all cases, the exposed filaments were decorated with the heavy meromyosin forming the well known arrowhead structures similar to those obtained by decorating F-actin filaments¹⁹ (Fig. 1c).

These results show that one component of nemaline rods, the lines running the length of the rod and responsible for the periodicity parallel to the long axis of the intact structure, is composed of actin. Partially exposed filaments that resemble those exposed with CAF can also be seen following extended (up to 40 d) low ionic strength extractions¹², but CAF treatment produces more complete exposure of filaments, does not remove portions of the longitudinal filaments as does low ionic strength extraction, and is much faster. These experiments suggest the usefulness of CAF as a probe of other structures that contain actin filaments. In particular, it would be interesting to use this method to examine the nature of rod bodies and widened Z line-type structures present in various skeletal and cardiac muscle disorders²⁻⁶ to see if they, too, contain an actin backbone.

Based on comparative electron microscope studies of cross sections of Z lines and nemaline rods, MacDonald and Engel⁸ suggested that I (thin) filament profiles are continuous throughout the rods. Engel and Gomez also had suggested earlier that the longitudinal filaments may contain actin because rods disintegrate when I filaments are extracted from the fibre⁷. From our long term selective extraction experiments on nemaline muscle with use of low ionic strength buffers, we concluded that the longitudinal filaments made up the backbone of the nemaline rod, but we were unable to identify their composition clearly¹². Note that our studies reveal only the composition of the longitudinal, filamentous backbone, they do not indicate whether tropomyosin or troponin are on the filaments in the intact rods. Nor do they directly indicate the composition of filaments or material responsible for the periodic lines perpendicular to the long axis of the rods; however, because antibodies to highly purified α -actinin bind to intact rods²² and because of the specificity of CAF in removing α -actinin from Z lines¹⁸, it seems likely that at least some of this material is α -actinin. Although Sugita *et al.*²³ reported that heavy meromyosin would not bind to nemaline rods, their result is not surprising because of the large amount of dense, amorphous material present in the intact rods that is removed by treatment with CAF.

Although it has not yet been determined whether actin terminates at the edge of the Z line or makes up part of the Z line structure in normal muscle, it is interesting that actin filaments are found throughout the rods of nemaline muscle. Stromer *et al.*¹² and MacDonald and Engel⁸ have suggested the rods can be considered to represent a replicating Z lattice or lateral polymer of Z line units. Further studies on nemaline rods may be useful in helping us to understand the Z line structure.
